It is pleasing to note that a great many of what are known as by-product coke-ovens are replacing the old form of beehive ovens, and by the manufacture of by-products some of the valuable qualities of these escaping gases are being extracted. Statistics show that the United States has yet in operation 90,000 beehive ovens, and in 1907 but 4,000 by-product ovens. The coke from the improved ovens in 1907 was valued at $21,000,000 and the by-products at $7,500,000. The beehive ovens in the same year produced coke worth $89,000,000, and in this manner absolutely wasted $55,000,000. Is it any wonder a stranger is astounded at this enormous waste, which can only be accounted for as due to the presumed abundance of their resources? Even with the modern oven as in use in Cape Breton to-day, the waste from poorly sealed oven doors, if thoroughly appreciated, should receive closer attention.

Very little coke-making was done in the Province of Nova Scotia in the early days, and any that was made was with beehive ovens. The Nova Scotia Steel & Coal Company, which had its pig-iron furnace at Ferrona, Pictou County, was the first in Canada to introduce the use of what is known as the modern retort oven. In connecton therewith was also built the first washery in Canada for the cleaning of slack coal.

About the year 1900, by-product coke ovens were built by the Dominion Iron & Steel Company in Sydney, and about the same time the Nova Scotia Steel & Coal Company built at Sydney Mines ovens of practically the same type: 30 at what is known as No. 1 Colliery, and 120 at its blast furnace, which is situated about half a mile from the colliery. Instead of utilizing the waste gases from these ovens for by-product purposes, this company chose to use it under its boilers as fuel, and the object of this paper is to give the members of this society an idea of how this was accomplished and the success it has met with.

This company is rather fortunate in having, what some people would call as a whole, "a self-contained enterprise;" that is, they own their own ore, limestone, coal, and metallurgical plant. By using these gases as a fuel, the result brought about a very peculiar and unique condition of affairs. It was found that, after supplying all the power that was necessary at the metallurgical end of the plant, some surplus power was available; this power was conducted back to the coal mines in the shape of electrical current, and is now being successfully applied in the underground hauling and raising of coal, and in furnishing power for the ventilating of the mines, forming what might be termed an endless chain in the operations.

The details of this plant will no doubt prove very uninteresting reading to a great many of our members, but, we hope, will be appreciated by persons who are directly interested in this class of work. Of course, there is no claim made by any officer of the Nova Scotia Steel & Coal Company that this undertaking was original or unique; but it is so surprising that such a small proportion of coke-makers have availed themselves of this method of treating with waste gases, that it was suggested to the writer that a paper of this nature might be of some value.

In connection with this plant, there are two independent installations of coke ovens: those near the blast furnace, known as the Bernard type, the surplus gas from these being used in connection with the production of steam for the electric power plant; the second installation of ovens of the Bauer type, located at No. 1 Colliery, the surplus gases being used in generating steam for general colliery use. These two installations are widely different in many respects, and between them they cover in many details the use of coke-oven gas under boilers.

In the case of the Bernard ovens, there are a number of small ovens situated at about an average distance of 200 feet from the boilers, so that the frictional resistance of this flue becomes an important factor when considering the amount of draft necessary. The gases pass through boilers of an ordinary fire-tube type, and here again the resistance of a number of small tubes is met with.

In the original design of this plant, the arrangement was such that the gases from 80 of these ovens were to pass through nine fire-tube boilers, and thence from a flue at the rear of the boilers to a brick stack 150 feet high, 6 feet 6 inches diameter, and with a stack temperature of 800 degrees F. a draft of 1½ in. water-gauge was produced. This stack would not produce sufficient draft to allow the ovens to work up to their full capacity, and this condition was further aggravated if it became necessary to take one or more boilers off for repairs, and it was finally decided that it would be advantageous to install an induced-draft fan between the rear flue of the boilers and the brick stack, and at the same time a number of the boiler settings were altered so that in the present arrangement there are nine plain fire-tube boilers, 15 ft. long, 8 ft. diameter, having thirty-nine 5 in. plain tubes and sixteen 5 in. screwed stay tubes.

The setting was altered on four of these boilers by building a brick wall longitudinally under the centre of the bottom of the boiler shell, so that the gas, after passing through the tubes from the front to rear, flows from rear to front under one-half of the shell, and through a port from the front to rear of the other half, and then from the flue at the rear of the boilers through the induced-draft fan to the stack.

This fan is of the regular type used for induced draft for boilers, having water-cooled bearings. The fan wheel is 108 inches diameter, 54 inches wide, and runs usually at about 220 r. p. m., and at this speed produces a draft equivalent to 1⅞ in. water gauge.

In the furnace of the boilers the draft is usually about 13-16 in., and in the main flue in front of the ovens is further reduced ¼ to 5-16 of an inch. The draft in the coking chamber of the ovens varies between ⅛ and 3-16 of an inch.

The 1⅞ in. draft at the fan, with the 9 boilers under steam, gives very satisfactory results; but if it is necessary to take off one or two boilers, the fan is speeded up until about 2⅛ in. water-gauge is produced.

The gas from any number of boilers can be cut off by dropping a damper between the main gas flue and the boiler. This damper consists of an iron band, the centre of which is filled with fire-brick; and as it works in a slot, the outer edges of the damper and the iron band do not come in contact with the hot gases, and the whole arrangement as a damper gives complete satisfaction.

Each of these batteries of 40 ovens was designed to produce 100 tons of 48-hour coke per day of 24 hours; but their capacity has been cut down by putting in an additional 2 in. fire-brick pavement in the bottom, so that their ordinary maximum capacity is now 90 tons. They can be charged with 7 tons of washed coal, containing about 8 per cent. of moisture, when properly levelled. This coal has an average analysis of about as follows:—

Ash	5.1%
Sulphur	1.2
Vol. matter	39.2
Carbon	56.7
Moisture	10.6

Under ordinary working conditions, before the change in the setting was made, the boilers would develop about 100 h.p. each; but, after returning the gas under the lower shell of the boiler, this was increased to about 112 h.p.

As a direct result of the use of the gas from two batteries of these ovens, the steam necessary for generating the electric power of the entire plant is produced, amounting to an average of some 260,000 k.w. hours per month, with engines of high-speed Corliss type having a steam consumption of about 16 lbs. of steam per 1 h.p.

At the Bauer coking plant the ovens are much larger and are located alongside the boiler-house, so that the gas flues are comparatively short, and the gas is used under Babcock & Wilcox water-tube boilers, offering very little resistance to its flow. These boilers are also fitted with an induced draft fan and discharge the gas into a stack 110 ft. high, 5 ft. diameter. In this case it is only necessary with three boilers on to produce a draft of 1¼ inches water-gauge; but if the gas is used under two boilers only, it is necessary to have a draft of 1½ inches.

With the same coal used for coking purposes, a test run on one boiler gave the following results:—

Average h.p. per hour	331
Maximum h.p. per hour	436
Minimum h.p. per hour	179
Coal charged into ovens during test	804,000 lbs.
Number of ovens charged	15
Evaporation from and at 212° per pound coal charged into the ovens	1.18 lbs. water
Coal charged into ovens per boiler h.p.	29.23 lbs.

The operation of this plant is giving very good results. And as these boilers have each 3,140 sq. ft. of heating surface, and generally the flue temperature at rear of boilers is between 600 and 700 degrees, it would seem that this proportion of about 9.5 sq. ft. of heating surface per h.p. developed, is about right for this class of fuel.

The electric power thus generated is used to operate lifting cranes at the blast furnace, trolleys that convey coke from the ovens to the blast furnace, electric coke-oven pushers, open-hearth cranes for handling all material for open-hearth purposes, electric open-hearth furnace charging machine, all the power necessary in the foundry, machine and car shops, electrically driving the coal washery plant, crushers, etc., ventilating No. 1 and No. 5 Collieries, operating haulage plant north and south at No. 5 Colliery, knocking screens and picking-belts at the collieries, lighting the whole plant, and in the many various ways that electric current can be used about a plant of such nature.

When one considers that this power only a few years ago was allowed to escape into the air, and at too many places is still allowed to escape, and when one considers the enormous amount of work that is being done by this power at the small plant described above, it is no wonder that the question of the utilization of this power is forcibly appealing to the engineers of to-day.

MINING AND SMELTING CONDITIONS IN BRITISH COLUMBIA.

On March 22nd Mr. Thomas Kiddie, a metallurgist long and favourably known in the Northwest, was the guest of honour at a luncheon of the Canadian Club of Vancouver, British Columbia. There was an attendance of about 130, including many men prominent in financial, mercantile and industrial circles in the City of Vancouver. The chair was filled by Mr. Ewing Buchan, manager of the Vancouver branch of the Bank of Hamilton, president of the Vancouver Board of Trade, and vice-president of the local Canadian Club. Other invited guests interested in the progress of the mining industry were Mr. E. Jacobs, mining journalist, and secretary of the Western Branch of the Canadian Mining Institute, and Mr. Robert R. Hedley, formerly manager of the Hall Mines smelting works, at Nelson, B.C.

After the toast of "The King" had been honoured, the chairman called upon Mr. Kiddie, who on rising to address the meeting was given a very hearty reception. He read the following address:

Mr. Thomas Kiddie's Address.

Mr. Chairman and Gentlemen: The mining industry of British Columbia is a subject to which it is not possible to do even scant justice within the limited time at my disposal in which to address you to-day, so that what I shall say to you will be more in the nature of a brief review of this important subject that in any way a presentment to you of the facts and figures necessary to adequately convey an idea of the very considerable advances made in mining and smelting in this province during the last ten years, and the proportions to which mineral production has attained.

Of the present condition of mining many here are fully cognizant from personal experience, from long residence on the coast, and from a general knowledge of the subject.

Those of you who have graduated from the school of experience in mining recognize at once its great possibilities, its attractiveness, its fascination, and its extensive

scope for the acquisition of wealth. In order to realize this we have but to visit any of our western cities to see the monuments of successes achieved in mining, to see the business blocks, banks, hotels and residences built with money made by men interested in mining, to be convinced of the very substantial results which follow the successful pursuit of mining. These successes are primarily due to a class of men whom we may well stop to honour—the prospectors. These men, after years of persistent effort, generally under the great disadvantage of insufficient means, are in too many instances rewarded only by a pittance of the actual worth of their mineral discoveries. You, gentlemen, who represent the financial end of mining, would do well to foster the acquaintance of the prospector, and see to it that he gets a just reward for his work, protecting him against his possible ignorance of the many ways in which his property may slip through his fingers, always remembering that every mine was once a prospect, and that without the prospector the expansion of mining, in this or any other country, would speedily come to an end.

Conditions Affecting Mining.

As to the conditions affecting mining operations, you are all aware of the fact that the physical and economic conditions prevailing in the districts in which our mining operations are carried on are important factors in realizing on the value of an ore. It is therefore important to note some of the great advantages we enjoy in this direction.

First, the coast between Vancouver and Alaska is cut into by rivers, inlets and canals, stretching far into the interior, and giving easy access to the different mining centres; so that by means of aerial tramways the products of the mines are easily and cheaply transported to tidewater, where, with storage bunkers, even large vessels may be quickly loaded. Transportation by water ensures delivery of the ores to the different coast smelters at the lowest cost, or the tramways may deliver the ore direct into the mills to be treated by concentration, smelting or other processes, the product of these mills in the form of concentrates, matte, or bullion, to then be delivered by water transportation to the nearest railway.

The larger the cargoes handled, the cheaper the freight rates are, and I think we only realize this great advantage fully when we compare this free trade by water transportation with railway transportation, even under its best conditions. As an illustration, I may mention the fact that copper ores are being freighted from Alaska to coast smelting points, a distance of 1,000 miles, at $1.50 per ton.

Water Powers Being Utilized.

Another physical advantage which we enjoy is the numerous smaller water-powers usually found in our mining regions. These are being more and more conserved and utilized for mining and smelting purposes. Electrical energy generated from these water-powers is readily and cheaply distributed from the generating stations to the various points where power is required for mining, milling or smelting purposes, and once installed, power is provided at a minimum of cost, without the vexations attending the production of steam for steam power plants.

In due time we hope to see more of our larger water-powers on the coast utilized for industrial purposes other than mining.

The achievements in electrical engineering have been so rapid and the results so astounding that it may be no idle fancy to predict that the wireless transmission of high tension electricity may be an accomplished fact in the not too distant future. What such a consummation would mean for power, manufacturing, and lighting purposes, is well nigh beyond comprehension.

Great Areas of Coal.

Another prominent asset which we possess toward favourable mining and smelting conditions, and indeed toward all our industrial conditions, is our great coast coal areas. The established coal industry of Vancouver Island has been especially successful, both as regards development and management. On that island to-day prospecting for more coal is being vigorously carried on, no less than eleven diamond drills being at work for this purpose.

The development of the coal and coke industry of the province has been marked by a steady yearly increase, beginning with 81,547 tons in 1874, to a gross production of 2,400,000 tons in 1909. This satisfactory progress is largely due to the fact that the industry of coal mining has been carried on on better business principles than that of lode mining; in other words, it has not been the victim of such frenzied finance as has characterized so many of our metal mining ventures. Further, we have the fact that the coal areas are larger, more constant, and less subject to change than lode mines are.

In addition to the Vancouver Island coal measures, we have another great coal area on one of the Queen Charlotte Islands, which, ere long, will rank as one more of our valuable assets. The time appears to have arrived when the coal measures on Graham Island, of the Queen Charlotte group, will be developed to their fullest extent, to meet the growing demands for coal for steamship, locomotive and general industrial purposes, consequent upon the increase of business which will follow the opening up of the interior of the province by new railway systems now being established, and the increase of population by immigration.

Production of Coal.

The coal mines of the province have produced in all 1836 to 1909) about 30,000,000 tons of coal, valued at nearly $92,000,000, and rather more than 2,000,000 tons of coke, valued at $11,000,000, or in round figures a total value of $103,000,000. The net production of coal for 1909 was about 2,000,000 tons, and of coke 250,000 tons, together valued approximately at $8,500,000. A substantial proportion of this was from the coal mines of the coast district.

In addition to these coast coal resources, Mr. D. B. Dowling, of the Geological Survey of Canada, estimates that the coal areas of the Crow's Nest Pass district, southern and northern portions, contain the enormous quantity of 36,600,000,000 tons of workable coal.

Large Deposits of Iron Ore.

Following the coal, we also have large iron ore deposits, though as yet undeveloped. The recent sale of the Iron Mine, on Texada Island, with its estimated 33,000,000 tons of ore, to Duluth capitalists, and the prospective building of an iron and steel plant on this coast in the near future, are matters for congratulation as tending toward the establishment of an industry such as in other countries is taken as the index of industrial progress. What the successful introduction of iron and steel making means to the coast and the province generally, you, gentlemen, are well qualified to judge.

In addition to these coal and iron resources, we have prospective new mining camps to the north, and judging from public and private reports from Portland Canal district, we will have a large mining camp there, for already the ore veins have been proved to a depth

of 300 feet, the ores being of two kinds, lead-silver and copper-gold.

Injurious Effects of Wild-Catting.

While I am optimistic as to the future of Portland Canal district, we must not blind ourselves to the probability, almost the certainty, that the wildcatter will be there in all his glory. Already he is gathering in his victims while the snow covers the ground to a depth of ten feet. Those of you gentlemen, who had the pleasure of listening to an able address in this hall two weeks ago, will recall the remarks of Mr. J. G. Colmer, when he said that while British capitalists appreciate "Canadian investments" they do not want "Canadian wildcats." The mining journals of this and every other country are constantly exposing wildcat mining schemes, and I venture the opinion that this same wildcatism has done as much to damn legitimate mining enterprise in this Province as anywhere else.

Insufficient Cash Capital.

Another cause of the failure of so many of our mining ventures—I refer especially to the orthodox $1,000,000 mining companies—is the lack of cash capital subscribed to do the necessary and actual development work, and provide the machinery requisite to make the enterprise a commercial success.

According to the best authorities on the subject, it is estimated that only three per cent. of the $1,000,000 capital is used for the actual development and equipment of a mine. In other words, the sum of three cents is expected to pay ten to twenty per cent. interest on one hundred cents.

It is almost a consensus of opinion among mining men, that the want of capital with which to prosecute the initial stages of mining is the most prolific cause of failure, and just why mining stocks should be sold for five or ten cents on the dollar is as incomprehensible as why a man should seriously invest in mines without any personal knowledge of the subject, professional advice, or knowledge of the character of the men at the head of the promotions. Let us hope the time is not far distant when these pitfalls in mining will be remedied either by common consent or by law.

Prospects of the Mining Industry.

Of the prospects of mining in the coast district, I invite your attention to the fact that some of the older mines on Texada Island continue to ship ore regularly with profit to their owners, and that the ore bodies which a few years ago were considered "pockets" have been proved to a depth of 1200 feet, and, in one case —that of the Marble Bay Mine—there is enough ore blocked out to last three years without doing any more development work. At Hidden Creek, in Portland Canal district Mr. M. K. Rodgers, has opened large bodies of copper ore, and it is fairly safe to say that his mine can at any time enter the list of shipping mines while in other directions along the coast some very promising properties are also being brought forward.

As to the prospects of mining in the upper country, the large additions made, or to be made, to the smelting works at Trail, Grand Forks, and Greenwood, will undoubtedly result in a substantial increase over last year's production as regards both mining and smelting.

Improvements in Smelting and Other Conditions.

It would be entirely out of place at this time for me to go into the technology of this subject, so it must suffice that I point out that substantial progress has been made in smelting during the past ten years. This advancement is seen most clearly when it is considered from the financial standpoint. An example of a copper ore that was sold to a smelter ten years ago is an illustration. The ore contained 6.3 per cent. copper, it yielded just $1 per ton to the seller after having paid a smelting charge of $6 per ton. To-day this ore would net $8.60 per ton, the smelting charge now being $2, and other deductions in proportion. A second case was where an ore assayed 6.3 per cent. copper; it was charged $7.25 per ton for smelting, which left a deficit of 25c per ton. To-day, owing to much reduced smelting, refining and other charges, this ore would net the mine owner $9.74 per ton. I think, gentlemen, these actual examples forcibly explain and illustrate the metallurgical advances which have taken place in smelting during the past ten years.

These improvements are due entirely to the metallurgist and the smelting companies, and the benefits derived from this advance have been applied to a reduction of the smelting charges, and so entirely to the benefit of the mine owners, as it enables them to ship at a profit low-grade ores which ten years ago would have been thrown on the dump as waste, or as a concentrating ore, to be treated at some more convenient season, after the requisite facilities shall have been provided. In view of the reduced cost of smelting, it follows that probably many of the prospects which ten years ago could not be made to pay would yield profits under our present more favourable conditions.

Improvements in ore dressing and concentration have also made great strides toward higher recoveries, both of the precious and the base metals, as well as reduction in operating costs.

Higher Percentage of Metals Recovered.

I remember, in 1890, when a recovery of 50 per cent. of the value of an ore was an average quantity. To-day, by means of improved methods, an average of 80 per cent. recovery is not at all uncommon.

In addition to the higher mineral values being recovered to-day as compared with the past, the time may not be far distant when other metals, such as zinc, which heretofore have been looked upon as an impurity and a detriment, will become sources of revenue. Already the Provincial Government has done a great deal toward a solution of this problem, while the Dominion Government now has under consideration a practical investigation of the subject of zinc separation. The latter, if successful, will add materially to the value of the mineral output of the province, and to the profit of the mine owners, who instead of being penalized $2 per ton for 12 per cent. zinc as at present, will receive a fair value for their zinc as they do to-day for their gold, copper and lead.

Relative Importance of the Mining Industry.

At the present time, more especially in the coast cities, the abnormal activity in real estate appears to overshadow mining and other legitimate industries, which go to develop the natural resources of the province, but it is only reasonable to presume that capitalists must sooner or later turn their attention to the further exploitation of these resources, which, aided by modern means of transportation have built up the Province of British Columbia until the combined annual value of its timber, minerals, fish and agricultural products amounts to $82,500,000. As still further proving the intrinsic value of the mining industry to the Province, I have only to point out that its production

almost equals that of the lumber, fishing and agricultural industries combined.

Figures of Comparative Production.

In order that you may better realize that great progress has been made, and that the average annual value of the mineral production of the province during recent years has been quite large, I submit the following facts and figures:—

British Columbia's mineral production in the year 1885 was of a total value of only about $2,000,000. Reviewing the increase in periods of five years each, during twenty years, 1889 to 1908, inclusive, the following results are obtained:—

Five Year Periods.	Average Annual Value.	Percentage of Inc.
1889 to 1893 inclusive.....	$3,700,000	85%
1894 to 1898 "	10,750,000	190%
1899 to 1903 "	17,500,000	62%
1904 to 1908 "	24,000,000	37%

It should be noted that lode mining did not begin to be of importance in the province until the second five year period above shown.

The aggregate value of the mineral production of Canada for 25 years to the end of 1909 was 1035 million dollars. For the first year of this period, namely 1885, the total was approximately $10.000,000; for last year, (1909,) it has been estimated by the statistician of the Dominion Department of Mines, at $90,000,000. During all years to date the aggregate production of minerals in British Columbia is of a value of $350,000,000. During the 25 years period above mentioned British Columbia has contributed about $285,000,000, or nearly 28 per cent. of the aggregate for the whole Dominion. The production of this province in 1909 constituted in value rather more than 25 per cent. of that of the Dominion, so that, notwithstanding the large increase recently made by Ontario, British Columbia continues to well maintain a prominent position in regard to its proportion of the mineral production of Canada.

In conclusion, gentlemen, it is not so much what we think of our province and its immense possibilities, but what those on the outside think. It is well to "see ourselves as others see us," to which end I quote the opinions of a Canadian, an American, a Welshman, a canny Scot and an Englishman, each of whom is highly qualified to give an opinion. The following are the comments of prominent visitors who were on this coast with the Canadian Mining Institute Summer Excursion party in September, 1908:—

By Mr. J. McLeish, statistician, of the Dominion Department of Mines, Ottawa: "Perhaps the most vivid impression left with the writer will best be expressed by the words 'magnitude' and 'possibilities.' By 'magnitude' I do not mean so much the absolute magnitude of our mineral production, although it is an important feature of our industrial economy, but rather the vast extent of the country throughout which mineral production and prospecting is being carried on, and the still greater area not yet even prospected; and this vast extent of territory at once suggests the great future possibilities of the mining industry which must unquestionably accompany the growth of population. As an illustration of this idea we saw..... in British Columbia the great copper deposits of the Boundary district, the gold-copper ores of Rossland, and the silver-lead and zinc ores of Slocan and East Kootenay, which are but the forerunners of an enormous mineral development that will extend throughout the length of the province from the United States boundary, on the south, to the far Yukon, on the north. At Frank, Coleman, Fernie, Bankhead, and Nanaimo we saw great coal-mining operations.....enormous areas of fuel resources. What may not be the future of these, as well as those other coal areas of whose values we are only just beginning to learn—the Brazeau, the Peace River, the Bulkley Valley, the Queen Charlotte Islands, and the coal fields of the Whitehorse district in Yukon Territory."

By Dr. Heinrich Ries, Professor of Economic Geology, Cornell University, U.S.A.—"No one thing or feature of the trip can be singled out for emphasis, for I was impressed from beginning to end with the wonderful mineral resources which we passed in review, and the intelligent energy with which they were being developed, factors, all of them, insuring a great future for the territory which we visited."

By Mr. Roger Beck, Swansea, South Wales:—"At Rossland and Phoenix, not blessed with rich ores, it was particularly noticeable how ingeniously the management of the mines and smelters had combatted the poorer grade by cleverness of appliances dealing with it. The automatic competing with labourer, and water with fuel in motive power. Wherever the conditions were unfavourable, ingenuity had done and was doing all possible to counterbalance."

By Mr. Sam Mavor, member of the Institution of Mining Engineers, Glasgow, Scotland:—"Canada has a great place, present and potential, as a mineral producing country. In addition to the minerals now in sight is the certainty of other similar discoveries, and beyond these lies the vast expanse of unprospected and even unexplored territory. The features which most forcibly strike the observer are the modernity of the important mineral industries, the energy and rapidity with which the great coal, iron, and copper mines are being developed, the courage exhibited in attacking low-grade ores, and the technical and administrative skill which have established sound industrial concerns upon low-grade ore bodies."

Mr. Hugh E. Marriott, at Vancouver (luncheon to C.M.I. party) Sept. 25, 1908:—"After all, what do **you** know of your own country? You know intimately the history of each camp that is now established and you can size up their chances more effectually than can be done by the stranger though he spend months of investigation instead of days. But when you look at these known spots on the map, they are but a very small section of that great stretch that remains unknown alike to you and me .....it must not be considered for a moment that your pioneers have chanced upon the only valuable mines or even the best. There must be hidden beneath that carpet of peat and verdure many a mineral deposit waiting the lucky chance of the prospector's pick or shovel. The question is; how are these to be found, so that at the earliest opportunity they can be made to assist in the building up of the nation and in advancing the prosperity of the land?"

After a hearty vote of thanks to Mr. Kiddie, whose address was listened to with close attention and frequently applauded, the proceedings terminated.

The average cost of diamond drilling per foot, with the drills operated by the Department of Mines of Nova Scotia was, during 1909, 79 cents; the corresponding cost per foot for calyx drills was $2.17.

OUR LONDON LETTER.

The Colliery Situation in Great Britain—Profits Still Falling, but not yet Below the Ante-Boom Level—Gas Perception Training for Colliery Firemen—British Miners Discuss the Royal Commission on Mining — Streamers in Cornwall — Rhodesian Shares on the London Market and the Revival in Chartered — Lessons of the Transvaal Complete Year.

London, March 18th, 1910.

A survey of colliery profits in this country shows extraordinary fluctuations in net profit figures comparing the last two years' accounts, and also urges upon the attention of the observer that the coal industry is one confronted with many difficulties. In the first place there has been no slackening in the fall in prices which commenced in 1908 after the last boom. In some collieries there has been a decline of thirty per cent in price, whilst the average decline of values in the export trade has been over ten per cent.

On the top of everything else has come the Miners Eight Hours Act considerably increasing the cost of production, and causing all kinds of delays pending the adjustment of working conditions to the new situation last year. Of course, the act was only in partial operation both as to time and districts in 1909, and it has further to be borne in mind that what is usually meant in the coal trade when a restriction of production is spoken of is that it has not increased at so rapid a rate as would have been the case if there had not been parliamentary interference.

A survey of the accounts of fourteen collieries, mainly in South Wales, shows that nine companies are worse off than previously, three are better, the remaining are showing no change. The Albion Steam Coal Company drops in the two last years from a net profit of $129,000 to a loss of $105,000, and of course passes its dividend. Andrew Knowles & Sons show a net profit reduction from 251,000 to $119,000, and the Cambrian Collieries' net profits fell from $835,000 to under $200,000. The Powell Duffryn Steam Coal Company shows a reduction in net profits from $1,350,000 to $921,000. These are typical of the losses.

The few companies which show increased net profits cannot compare in any way with these figures. Of these three companies one maintains its dividend unchanged, one advances it from 12 1-2 per cent to 17 1-2 per cent, and the other actually dropped from 10 per cent to 5 per cent, but slightly increases its carry forward. From these average results the result is arrived at that the aggregate profit is down about 40 per cent as compared with twelve months ago, and 50 per cent as against two years ago. In that year 1907, however, it has to be remembered distributable earnings went up nearly 90 per cent on the previous year, so that all these concerns are still comfortably above the level of the period immediately preceding that extremely remunerative season.

Whilst on the coal question mention might be made here of a rather important meeting of the National Association of Colliery Managers held at Manchester University on March 4th. The chief business was the description by Mr. George H. Winstanley of apparatus designed to meet the recommendation of the Royal Commission on the need for some means of training colliery firemen in accurately estimating the presence and quantity of gas. Mr. Winstanley said the development of deep mines meant high temperatures and considerable dust, and it was from the presence of dust that danger of disastrous explosions arose. There was one certain way of avoiding explosions of gas, that of full ventilation. The improvement of ventilation had reduced explosions of gas to very small affairs, but there was considerable danger of those small affairs leading to explosions of dust far more disastrous than the biggest gas explosion on record.

The experiments at Northallerton had shown that a small explosion of gas made it easier for an explosion of dust to occur, and it was with the desire to prevent the small disturbances that he had arranged an apparatus which supplied a known amount of gas to an ordinary safety lamp. It was easy for any one to take observations of the "cap" to the flame formed by the combustion of gas, but under ordinary conditions the varying power of different individuals to distinguish colors made accurate estimation of the quantity of gas very difficult. When known quantities of gas were supplied, however, a few experiments gave the power of judging very accurately what percentage of gas gave a given "cap" to the flame.

Leading representatives of the workmen's side of the British mining industry met in special convention in London on March 15th to consider the report of the Royal Commission on Mining. The conference was held with closed doors, but an official report issued declared that the conference was in complete agreement on the questions which were discussed. It was generally agreed that the sittings of the Royal Commission on Mines should be continued, and that their investigations should be specially directed to the dangers attending upon coal dust and the use of electricity in mines. It was stated that the special representatives of the Miners' Federation appointed to attend the inquiry into the West Stanley colliery disaster, by which 160 lives were lost, had reported that in their opinion this disaster was attributable to the use of the electrical installation.

On the important questions which the Royal Commission have already reported the conference was agreed in supporting the claim of the colliery enginemen for a statutory eight-hour day in the same way as the underground workers, and also in their demands that all enginemen filling these responsible positions should hold certificates of competency. It was stated that the responsibilities of the enginemen had been enormously increased by the deeper working of the pits and by the larger number of men employed. The working in some of the pits of two and three seams of coal at different levels, with the requirement to control the engine working at the various levels, has made the work more difficult, the slightest error involving the loss of human life. It is thus felt that no man should be employed in charge of the engines who has not previously obtained a certificate of competency. With the heavy demands now made upon the enginemen they should have the same statutory protection as the miner of a legal eight-hour day. At present some of the enginemen work eight hours, while others work longer.

A curious small mining industry in this country is carried on in the Cornish tin district on the Red River. There a class of individuals called streamers are at work recovering black tin. Each streamer holds a section of ground. The waste tailings and slimes from the Camborne mines pass into the river and leave a concentrate of black tin, with its attendant minerals, of which it is

the business of the streamer to recover as much as possible from his holding. There are sixteen different firms or individuals at work, and these recover about 800 tons of black tin annually. The residuals pass into the sea, to be still further concentrated by wave action, and at low tide these concentrates are collected by the streamers. Nature, therefore, acts as a more complete concentrator than the elaborate machinery of the mines, and proves the need for greater efficiency to prevent this loss to them of valuable metals.

The mining market in London has been endeavoring in recent weeks to obtain a share of the speculative activity aroused in the first place by the extraordinary boom in rubber shares. The Rhodesian section has made progress but not enough to satisfy that faithful following which has been hoarding Rhodesian shares for years past, in the hope that one day they will get back to the prices they originally paid for them. All the same it is truly surprising to find Chartered again over $10 a share. This share is the mining description in which the average British mining investor is more fully interested than in any other. Its present authorized issued capital is nearly $31,000,000. In the great old palmy days of Cecil Rhodes, most of these shares were unloaded on the public here at all kinds of high figures up to $40 per share—a share having a face value of $5. After years of decline the bottom was reached two years ago, when the shares were quoted no higher than $2.50.

The figures now to hand dealing with the complete mineral production of the Transvaal for last year are calculated to revive any flattened interest our investors may have had in South African Gold Mines. The gold yield of the Witwatersrand does not show so great an increase as was anticipated a year ago, but, production was hampered by the abnormal rains which fell in the early months, and by an insufficiency of native labour in later months. Nevertheless, it must be admitted that the advance in the gold output is both substantive and satisfactory, and when the details of the work are examined there is little room to complain of the future prospects of the industry.

The salient features of the year's work are a larger tonnage crushed by a larger number of stamps and tube mills operated by practically the same number of persons, though a larger proportion of whites to colored were employed in 1909 than in 1908, according to the December returns for each year. A higher average stamp duty of 52 tons per stamp per day was obtained from an increase in the average number of stamps operated of 567, and an increase of 45 in the average number of tube mills.

The average value of the tonnage treated throughout the year for the Transvaal was twenty-nine shillings and one penny per ton as compared with thirty-one shillings and sixpence per ton for 1908, a decline of two shillings and fivepence per ton, while for the Witwatersrand the figures read:—1908, thirty-one shillings and fivepence; 1909, twenty-eight shillings and elevenpence, or two shillings and sixpence per ton less for last year. It has been frequently explained that the continuous fall in grade is very largely intentional through the reduction in working costs, bringing rock previously classed as unpayable, and hence allowed to remain untouched, into the payable margin. This fall in the grade of ore treated will naturally follow the fall in working costs, for that is the sole factor which governs the economic position. As an illustration of the gradual decline in the value of the ore treated, the figures for January show that the average value of rock sent to the mill on the Rand was twenty-nine shillings and ninepence per ton, while for December it was no more than twenty-eight shillings and fivepence per ton.

The total Transvaal working profit for 1909 was $60,371,510, a slight decrease on the previous year, but notwithstanding this the mines were able to set aside a bigger sum for dividends, distribution for the two periods being, for the whole of the Transvaal, $47,523,105 in 1909 as against $43,756,410 in 1908. In face of the fact that the total working profits for 1909 were $1,250,000 less than the preceding year, it is a distinct tribute to the improved efficiency and economy with which the mines have been worked that $3,750,000 more has been returned by the Transvaal in dividends and the still larger sum of $3,865,000 more by the Rand.

It may very properly be objected that there is a limit to the reduction of working costs and to the improvement in efficiency of treatment plants, as well as the quantity of ore to be won at a profit. But so far these three factors have not yet been determined. Nearly all competent authorities agree that working costs still offer a reasonable margin for attack; that treatment plants, notwithstanding that the latest installed have reached a high pitch of excellence, leave room for still further improvement; and that the quantity of payable ore yet to be exploited is not calculable, in other words, is unlimited.

STATEMENT BY TEMISKAMING MINE MANAGERS' ASSOCIATION.

An article by Dr. Eugene Haanel, Director of Mines Branch, Department of Mines, Ottawa, in the February number of "Industrial Canada," reflects disparagingly on the mining and metallurgical industries of the Cobalt region. The Temiskaming Mine Managers' Association makes the following specific comments on Dr. Haanel's statement:—

The statement "and in the Cobalt region . . . the mortality was simply astounding, the death rate per 1,000 men employed being 24.8," is absolutely without foundation or fact. Its incorrectness was known by those responsible for it, two months previous to its publication in the above periodical.

Notice of their error has still more recently been brought to their attention, both publicly and by the Ontario Department.

In issuing no formal correction, those responsible for the statement are to be condemned for their silence and for their defensive attitude.

The official figures on fatality, as determined by the Ontario Bureau of Mines, are:—

	Per thousand.
Cobalt producers, underground	12.
Cobalt producers, underground and surface	5.38
Cobalt area (proper), underground and surface	5.25
Area tributary to T. N. O. Ry., underground and surface	5.45
Province of Ontario, underground and surface	5.2

The figures given for Cobalt, in the report for 1909 of the Ontario Bureau of Mines, refer only to producing mines. We cannot see why Dr. Haanel has seen fit to divide the number of underground fatalities in the entire area tributary to the T. & N. O. Ry. by the number of men working underground in the Cobalt producers, and officially announcing the resultant 24.8 as the astounding rate of fatality in the Cobalt region.

The statement, "The cobalt-silver ores certainly

need investigation, with a view of discovering a more rational method of treatment than is at present practised," is based, not on personal observations, but "on the report of a manager some years ago," and is entirely unwarranted, in view of the splendid results now being obtained at Copper Cliff, Thorold, and Deloro.

In making the above statements Dr. Haanel has falsely put the Province of Ontario in an unenviable position as regards her mining and inspection laws, which are well known to be the most rigourous and complete on the continent.

Recent criticism of the Mines Branch, in connection with the above statements, has done much to undermine the faith of mining men in its statistics and suggestions.

H. PARK,
President.
J. G. SHEWAN,
Secretary.

CANADIAN MINING INSTITUTE.

The following gentlemen were elected to membership of this Institute at the regular April meeting of Council, held on the 1st instant:—

Ex-Officio Members.

Dresser, John A., Geological Survey, Ottawa, Ont.
Frechette, H., Department of Mines, Ottawa, Ont.
Lindeman, E., Department of Mines, Ottawa, Ont.
Malcolm, W., Geological Survey, Ottawa, Ont.
Malloch, G. S., Geological Survey, Ottawa, Ont.

Members.

Carmichael, H. Graham, 515 Wellington St., Montreal, Que.
Chambers, A. R., Nova Scotia Steel & Coal Co., Trenton, N.S.
Gaul, Alfred J., 34 Yonge St., Toronto, Ont.
Hoffman, Bertram F., Cobalt, Ont.
Howell, Edgar N., Box 996, Cobalt, Ont.
Leslie, James, Supt. Cobalt Central Mines, Ltd., Cobalt, Ont.
McKay, Robt. B., Cobalt, Ont.
Plate, H. R., Box 474, New York City, U.S.A.
Raynor, Geo. W., Thorold, Ont.
Robinson, A. H. A., 497 Gilmour St., Peterborough, Ont.
Smith, W. H., Mgr. Bell Asbestos Mines, Thetford Mines, Que.
Sproule, Gordon St. G., 106b Stanley St., Montreal, Que.
Williams, Percy, 524 Mineh Block, Vancouver, B.C.
Wilson, Eugene B., Scranton, Pa., U.S.A. (Ed. "Mines and Minerals.")

Associates.

Graham, Robt., Giroux Lake, Ont.
McGregor, D. M., Junior Turf Club, 3 St. James St., London, S.W., Eng.

Student.

Cumming, James D., 114 Bedford Road, Toronto, Ont.

PERSONAL AND GENERAL.

Mr. T. Jones, representing the Buffalo Mine interests, has purchased one Nissen stamp for installation at Porcupine.

Mr. James Hargreaves, formerly superintendent of the Alberta Consolidated Coal Company, near Taber, Alberta, is in Toronto.

Dr. Richard V. Mattison has resigned from the Board of Directors of the Amalgamated Asbestos Corporation, Limited. Dr. Mattison is president of Bell Asbestos Mines.

WORKING COST COMPARISONS.

At the annual meeting of the Mine Managers' Association held at Johannesburg the following reference was made by the President to working costs on the mines of the Witwatersrand:—"Our present basis of comparison between mine and mine and month and month—namely, the 'cost per ton milled,' which is dependent on so many factors, such, for instance, as whether or not it has been possible to keep the mill supplied with rock; whether the first day of the month happens to fall on an early or late day of the week, for on this depends whether more rock has been crushed in relation to the quantity mined or vice versa; and whether or not the machinery has run well. There is another grave disadvantage in this basis of comparison and that is the inducement to bring down costs illegitimately by the carrying of stopes wider than need be for maximum profit, or the skimping of sorting, and the hundred and one other things on which good mining really depends, merely to be able to show low working costs. If a system were generally adopted whereby a comparison of profit derived from areas exploited were made the basis of comparison, we would, I know, show higher cost per ton crushed, but the Rand would also, I believe, show a greater profit per area denuded of its valuable product, and that, I feel sure, is the thing we are all, or should all, be striving for. The scheme outlined above is, I understand, being introduced into the Corner House mines at once at the suggestion of Mr. H. F. Marriott, and we may therefore hope that before long the bogey of 'cost per ton milled' will have permanently scotched, to be replaced, as a 'divisor' by the much more accurate 'square fathom exploited.' But when all is said and done as regards basis of comparison the main thing to remember is that no two mines, or even the same mine at different periods, are really similar conditions, and that therefore comparison on a cost or a profit basis is most dangerous, except to those fully informed of the circumstances of both, and that the financial inclusion of two mines under one control does not of itself make comparison possible where conditions remain dissimilar."

The Engineering and Mining Journal, April 9, 1910.—In the course of a very sane editorial entitled "The Coal Miners' Demands" strong exception is taken to the miners' request that coal be paid for on a run-of-mine basis. This "from every standpoint, and especially that of economy and safety, . . . is to be severely condemned. For years coal has been paid for on a screened-coal basis, and this has been an incentive to the better preparation of the daily output. To go back to a mine-run basis would encourage shooting from the solid, with its resulting waste and dangers."

The Mining World, April 9, 1910.—"The 'Factor of Safety' in Mine Sampling" is the text of a symposium of opinion published in the current number of our contemporary. In response to questions put before them by Professor Arthur J. Hoskin, of the Colorado School of Mines, expressions of opinion were elicited from certain students, and in these opinions there is much diversity. That arriving nearest the truth, and nearest also the average of what each is driving at, is one opinion that concludes thus: "No general rule can be followed in discarding exceptional assays, including them as they stand, or applying to them a factor of safety. It is safe to say, however, that the wise course to follow is to take all possible precautions and then trust to common sense."

THE FIXATION OF ATMOSPHERIC NITROGEN AND THE FOOD SUPPLY.

LEO FRANK GUTTMANN,

In 1896 when addressing the British Association for the Advancement of Science, Sir William Crookes drew the attention of the entire civilized world to the question of food supply. He first of all pointed out that the increase in populations was so rapid that in a few years there would not be sufficient land available to grow the wheat required to feed them. In order to feed the coming millions, it would be necessary to increase the yield of wheat per acre, by the use of artificial fertilizers containing nitrogen. But the main supply of these, the sodium nitrate or Chile saltpetre beds of South America could not last forever, in fact their exhaustion was predicted in a short number of years, say 40 to 50, and where would we be then? The importance of this question can best be illustrated by quoting from Sir William's presidential address, the facts adduced in 1898 requiring little alteration for present purposes.

"The present acreage devoted to the world's growth of wheat is about 163,000,000 acres. At the average of 12.7 bushels per acre, this gives 2,070,000,000 bushels. But thirty years hence the demand will be 3,260,000,000 bushels, and there will be difficulty in finding the necessary acreage on which to grow the additional amount required. By increasing the present yield per acre from 12.7 to 20 bushels, we should, with our present acreage secure a crop of the requisite amount. Now from 12.7 to 20 bushels per acre is a moderate increase of productiveness, and there is no doubt that dressing with nitrate of soda will give this increase and more.

"The action of nitrate of soda in improving the yield of wheat has been studied practically by Sir John Lowes and Sir Henry Gilbert on their experimental field at Rothamsted. This field was sown with wheat for thirteen consecutive years without manure, and yielded an average of 11.9 bushels per acre. For the next thirteen years it was sown with wheat, and dressed with 5 cwt. of nitrate of soda per acre, other mineral constituents also being present. The average yield for these years was 36.4 bushels per acre—an increase of 24.5 bushels.

"At this rate, to increase the world's crop of wheat by 7.3 bushels, about 1½ cwt. of nitrate of soda must annually be applied to each acre. The amount required to raise the world's crop on 163,000,000 acres from the present supply of 2,070,000,000 bushels to the required 3,260,000,000 bushels, will be 12,000,000 tons distributed in varying amounts over the wheat-growing countries of the world.

"If we assume a liberal estimate for nitrate obtained from the lower-grade deposit (the Chile saltpetre beds are meant,), and say that it will equal in quantity that from the richer quality, the supply may last, possibly, fifty years, at the rate of a million tons a year; but at the rate required to augment the world's supply of wheat to the point demanded thirty years hence, it will not last more than four years."

One other illustration, from French statistics, to illustrate the vital importance of the problem. The crops harvested in France abstract annually 600,000 tons of nitrogen from the soil. It is proved that the nitrogen returned as stable manure, supposing it were all taken back to the fields, would not amount to more than 327,000 tons. Now France consumes only 230,000 tons of Chile saltpetre per annum, representing 31,200 tons of nitrogen, whilst the deficiency is 273,000 tons. The amount imported is thus only 11 per cent, of the deficiency produced by the removal of the crops.

The address of Sir William Crookes having called general attention to a vital problem, inventors at once set to work to obtain this necessary nitrogen, and turned to the enormous amount of nitrogen in the atmosphere for their source of raw material. The amount of nitrogen in the air over a field of nine acres is about 280,000 tons, i.e., the same amount which is contained in the 1,740,000 tons of Chile saltpetre exported in 1907. The practically inexhaustible supply of nitrogen in the air totals about 4,041,000,000,000,000 tons.

In their classical researches on the constitution of air, Priestley and Cavendish in 1775 caused oxygen and nitrogen to combine by passing an electric spark through the mixture for a continuous period of about forty hours. The nitrous acid thus formed, was absorbed in a solution of caustic soda, forming nitrate and nitrate of soda. Over one hundred years later, in 1897, Lord Rayleigh and Sir William Ramsay isolated the new gas, argon, by treating large quantities of air in a glass vessel, with the electric spark. Priestley had treated 100 cubic centimetres of air (about 7 cubic inches) for forty hours with an electric spark, obtained by turning an induction machine by hand. Rayleigh and Ramsay "sparked" twenty litres, two hundred times as great a quantity, in an hour by means of an automatic induction coil. On this principle the modern method of fixing nitrogen as nitric acid is based, but enormous quantities are involved, the work situated at Notodden in Norway treating 75,000 litres, (nearly 3,000 cubic feet) of air per minute.

The principle having been established, practical means had to be devised. Of these, I shall only mention five. The problem in the combination of nitrogen and oxygen is twofold, the mixed gases have first to be heated to as high a temperature as possible, up to 3,500° Centigrade (6300° Fahrenheit) by passing through an electric flame, and they have then to be cooled as rapidly as possible, to minimize the decomposition which unfortunately sets in at an intermediate temperature of about 600° C. (1080° F.). To accomplish this, Bradley and Lovejoy at Niagara Falls, devised an ingenious apparatus consisting of a cylinder studded internally with platinum points, inside of which revolved another cylinder, studded externally with platinum points. Each cylinder was connected to the electric circuit, and the effect of the arrangement was to produce a countless number of small electric arcs, an arc being formed each time two platinum points came in contact. About 414,000 arcs per minute were thus produced in an apparatus using only a small amount of electric energy, and thus a large volume of air could be successfully subjected to the effect of the electric spark. Although a fair yield of nitric acid was obtained, this process did not prove a commercial success.

The other processes to be described, make use of the electric arc instead of the spark. If a current of air is rapidly blown through an electric arc, the oxygen and nitrogen combine, but the yield thus obtained is small, the concentrated heat of the arc offering only a small

surface of action to the gases. Means had therefore to be devised to increase the area of the electric arc, and this problem seemed almost impossible of solution, till Birkeland and Eyde in Norway, showed how it could be done. They took an ordinary electric arc, of enormous energy (up to 1,300 horsepower) and allowed it to play in a space set equatorially, i.e., in a plane at right angles—to the poles of a powerful electro-magnet. The effect of this is to spread out the electric arc to an enormous flat disc of flame, the actual electric flames used being 7-12 feet in diameter. Each flame is surrounded by a chamber of fire-brick, forming a furnace, and resembling a huge cheese standing upright. Air is blown in through perforations in the brick lining at the rate of 1,000 cubic feet a minute, and withdrawn laden with oxides of nitrogen through another opening. The arc electrodes are of copper, cooled by circulating water through them, and the working potential is 5,000 volts with a current of 200 amperes. The flame, when burning, emits a loud noise, but requires very little attention to keep it in good order. The subsequent treatment of the air laden with oxides of nitrogen, will be described further on. The Birkeland and Eyde process is at work at Notodden, Norway, where large amounts of water power or "White coal," are available at the cheapest rates in the world. The yield of the process is good, and the price of production low enough to compete with Chile saltpetre. The power at present used in Notodden amounts to 30,000 horse power.

Another commercially successful process is that of H. and G. Pauling, worked by the Saltpetersaure Industrie Gesellchaft. Their works are situated at Patsch near Innisbruck, in the heart of the Tyrol, and utilize 15,000 horse power. I had the privilege of spending three days last summer in this charming spot, investigating the process. The factory lies in a little valley, surrounded by high and picturesque mountains, the Brenner railway passes over a viaduct on the other side of the valley, the river Sill runs through it. The water is taken from the Sill, conducted through a canal six miles in length, and utilized at a fall of 600 feet. In this process air with a high velocity is blown through a nozzle between two horn-shaped iron electrodes, these being water-cooled. The effect of this is to blow out the electric arc into a great roaring sheet of flame, over 3 feet long, and thus offering a large surface of contact between the flame and the air. The sight of this huge flame is terrifying but harmless. The flame plays inside an ordinary brick furnace, the air laden with oxides of nitrogen being drawn off by a fan to the absorption towers. This process was working on a manufacturing scale at a time when the Birkeland and Eyde process was still in the experimental stage.

It is exceedingly difficult to obtain any accurate information regarding the actual yields and working costs of the various systems described, these being kept secret, but it may be mentioned that the Birkeland and Eyde, the Pauling process and the Cyanamide process have been proved to be successful on a large manufacturing scale; and sums of $50,000 for an option on the process in a particular country with royalties of upwards of $100,000 a year, seem to tell the same tale. The Pauling process is exceedingly simple and the yields are said to be as good as those obtained by the more complicated Birkeland Eyde process. Factories utilizing 50,000 horse power are in course of erection. The treatment of air, carrying oxides of nitrogen being the same in these processes, and in that of Schonherr (see below) will be described at this point. The air is cooled by suitable means, and passed up 3-5 large towers, 6 feet in diameter, 30 feet high, built of granite or volvic lava, and filled with quartz pebbles, over which trickles a continuous stream of water. In contact with the water, the oxides of nitrogen are converted into nitric acid, and by constantly circulating the water, nitric acid of 30 to 40 per cent. strength is obtained. To be made into a merchantable product this has to be concentrated. Concentration at 60 per cent. is easy, further than that it is very difficult, and yet the chief consumer of nitric acid, the explosives industry, requires acid of 99 per cent. strength. It is this that constitutes the weak spot in all these processes. At the Notodden works the nitric acid is treated with limestone, and the resulting nitrate of lime sold as an excellent fertilizer, competing with Chile saltpetre. But freight charges are heavy. In all the processes the final absorption of the oxides of nitrogen is made with sodium carbonate solution, or milk of lime, nitrate of soda, or nitrate of lime respectively, being obtained. But the market for nitrate of soda, is exceedingly limited, the world's total consumption being about 2,000 tons. Incessant attempts are being made to obtain more useful products, and will doubtless prove successful.

The most recent process of this class is that due to Schonherr, of the Badische Anilin and Soda Fabrik. He forces the electric arc to take a spiral path, and thus increases its length to six feet and more, the air blown in being made to travel along the arc. The yields of this process are very good, the subsequent working up of the products being as already described. An amalgamation has taken place recently between the Birkeland and Eyde, and Badische companies, joint works will be built and in a short time 400,000 horse power will be utilized in the fixation of atmospheric nitrogen by these processes.

We will now consider a process of quite a different type, that of Professors Frank and Caro, of Berlin. If atmospheric nitrogen, freed from Oxygen, be passed over calcium carbide heated to about 600° Centigrade, (1,100° F.) absorption takes place, no further heating being required, and a compound called calcium cyanamide is formed. The reaction is simple, requires very little heat expenditure, and calcium carbide is a cheap electrical product now manufactured on a large scale. This calcium cyanamide contains fixed nitrogen, and contains about 22 per cent of this element, that is, about the same amount as is present in ammonium sulphate. And of ammonium sulphate 600,000 tons were manufactured in 1907, in England alone, for use as a fertilizer. It remained to be seen whether calcium cyanamide could be directly utilized as a fertilizer and large scale experiments were made on spring wheat, winter wheat, winter rye, oats, Indian corn, potatoes and sugar beet. In every case the fertilizing effect of calcium cyanamide was proved to be equal or superior to that of ammonium sulphate or Chile saltpetre. All three, of course, produce very much greater crops than when no manure is employed. The product has been manufactured on a large scale for several years, and is sold under various names: e.g., nitro lime, lime nitrogen.

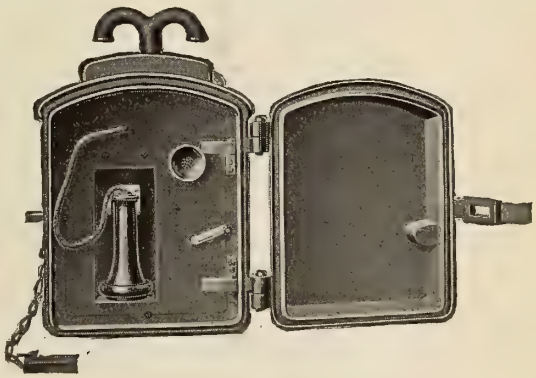
Nitro lime was not at first manufactured for direct use as a fertilizer. It can readily be split up chemically into ammonia, or salts of ammonia, and it was intended to use these salts of ammonia as an equivalent for the rapidly-diminishing amounts in sight. The idea, however, occurred to the inventors to let these chemical changes take place directly in the soil, instead of in the laboratory, and to use calcium cyanamide as a fertilizer, with the excellent results quoted.

The manufacture is simple. Thanks to the genius

of a Canadian, T. L. Willson, of Ottawa, the prime material, calcium carbide, is now obtainable in unlimited quantity and at a low price, he having been the first to make the manufacture of carbide a commercial success. The calcium carbide is ground fine and heated in a furnace, whilst nitrogen is passed in. Absorption is complete in about forty hours, and since the reaction is an exothermic one, very little heat is required to keep it going when once started. The finished product is ground, and when packed in suitable sacks, is ready for the market. The nitrogen required has been obtained in various ways; originally nitrogen was obtained by systematically fractionating liquid air manufactured according to Claude's of Linde's patents. Patents have now been taken out for the manufacture of nitrogen from producer gas, and by burning petroleum residues in air.

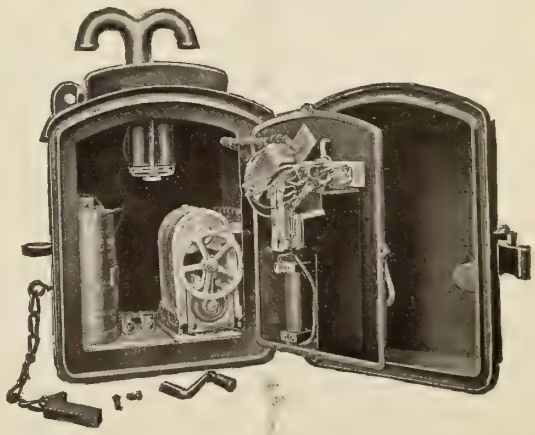
The utility of nitro lime does not stop here. It can be converted into sodium cyanide, and large quantities of this material are already manufactured from it, and exported to the Transvaal and other gold-producing countries. The process has proved a commercial success and this is again shown by the large prices paid for options and manufacturing licenses. In brief, the process consists in fusing the calcium cyanamide with coke and salt, thus obtaining a mixture of calcium chloride and sodium cyanide. This mixture is sold as a "surrogate," and claimed to be cheaper and more efficient than pure sodium cyanide. To obtain cyanide, the mixture is treated either with sulphuric acid or with sodium bisulphate, and the prussic acid distilled off and absorbed in caustic soda. On evaporating, sodium cyanide is obtained. It is manufactured in the form of briquettes, which are more readily soluble than fused cyanide, and is sold as 125. per cent. cyanide on the potassium cyanide basis. Calcium cyanide can also be converted into numerous other products, such as urea and its derivatives, ammonia, etc. It is the most formidable competitor of the Birkeland Eyde Badische Pauling systems, and we shall see why. All these latter require much larger quantities of electrical energy at a very cheap rate, and the works have therefore to be located in Norway. You can thereby manufacture cheaply, but freight charges are heavy, and the product on that account can barely compete in European markets with Chile saltpetre. This Norway saltpetre will, however, ultimately be the substitute for Chile saltpetre. Calcium cyanamide however, seems destined to replace ammonium salts, and works aggregating 160,000 horse power are in course of erection, not in out of the way places, but wherever needed. 40,000 tons of nitro lime are at present manufactured yearly, and about 5,000 tons of sodium cyanide.

To sum up, for our rapidly-diminishing stocks of nitrate of soda or Chile saltpetre, we have as a substitute, fixed nitrogen from air, in the form of calcium nitrate or Norway saltpetre. For a like purpose, and as a substitute for the limited amount of ammonium salts at present available industrially, we have calcium cyanamide or nitro lime. All these products being manufactured by the aid of a power at present unutilized, the "white coal" of the world's waterfalls which will last as long as the sun gives us light, no apprehension need now be felt as to the world's food supply failing for lack of a fertilizer. A little reflection will show how gloriously Canada is provided with the acres to grow the world's food, and with the "white coal" wherewith to fertilize them. The warning uttered ten years ago by Sir William Crookes, has been heeded, and remedies devised in the incredibly short time since elapsed.



NEW MINE TELEPHONES.

The accompanying illustrations are views of newly developed telephone sets designed especially for use in mines. This apparatus is the result of many months of careful experimenting and testing on the part of expert engineers. The announcement of this new apparatus



comes at an appropriate time, as the many disasters of the past year in underground shafts have focussed attention upon the problem of safeguarding life in the mines.

Working in co-operation with mine operators and officials, the Western Electric Company in the design

of this new equipment has been careful to meet all the requirements of mine service. The quality standard of the "Bell" telephones, all of which have been made by this company, has been observed in the design of these new mine sets. The telephones are of two types—

No. .336-E, a metal set, and No. .337-E, a wooden set.

Three views of the metal mine telephones are shown in the accompanying illustrations. The wooden sets possess the same general features of arrangement and

operation. The cuts demonstrate the compactness and convenient arrangement of these telephones. All of the apparatus inside the case is accessible, yet at the same time it is carefully protected. The parts are easy to get at with a screw-driver. No soldering irons or torches are necessary in maintenance work.

The line wires to these sets may be brought in either at the top of the case or at the bottom. A feature in the wiring of the sets when connected to the line from the top is the curved connector shown in the illustrations. This connector prevents water and moisture from following the wires into the apparatus. It will be readily seen that as the wires come down to the set they make a curve into the connector, so that any moisture or water will drop from this point and not follow the wires into the set. When the line wires are brought into the bottom of the set the curved connector is not necessary, and the opening for it is closed by a suitable plug provided for the purpose.

The gongs used with these telephones give a loud, clear ring, which can be heard a long distance in the mine. They are protected by a hood, so that it is impossible for a falling body to injure them or interfere with their action.

Each set is equipped with the No. 48 5-magnet generator, recognized as the most efficient hand generator for telephone use on the market. Transmitter and receiver are of the familiar "Bell" grade type. Windings of receiver, ringer, induction coil and generator have been especially treated to protect them from acid fumes, gases and moisture.

That coal mining is the most hazardous industry in America is a statement that has often been made. The telephone, though nothing new for mine use, has recently been urged as imperative for proper protection against fires, and has always been found an invaluable aid to the conducting of business in the mines. The new telephones are important in that they represent a development through many tests and applications in the attempt to arrive at the complete instrument.

Correspondence.

The Editor, "Canadian Mining Journal."

Sir,—In your issue of April 1st I notice a paper by Mr. James Rennie treating of "Claims Assessment Work in the Province of Ontario." The question raised is a timely one,, and if your space will permit I should be glad to add a few remarks.

Under the present system the Act calls for a given number of days' work during the years until patent issues. Each day is to be of eight hours duration, and it is assumed than an honest day's work will result. Provision is also made for the inspection of this work by the Recorder. It is, however, manifestly impossible for the Mining Recorders to inspect all the claims in the various divisions, and I believe any inspection for work is rare. From a variety of causes then, it is possible to evade the just requirements of the Act. Under the system proposed by Mr. Rennie the claim holder will be required to record actual work performed, expressed in cubic feet. In short, the system of the present calls, in effect, for the putting in of time: the new system proposes a check on mere loafing, and dishonesty, and calls for work expressed in cubic feet—if not in foot-pounds.

Anyone who has travelled extensively through the northern part of Ontario will realize that the Mines Department is, in too many cases, being cheated of its moderate requirements in the way of assessment work. Many capitalists are letting out their assessment work on the contract plan, and though they are not getting their properties developed in any true sense, the system answers their purpose, because the contractor makes affidavit of the performance of the work, and thus the requirements of the Mining Act are fulfilled, too frequently at the price of a false affidavit! There are many honest contractors, it is true, but these are largely put out of competition by their dishonest brethren who assume the responsibility at a price which manifestly precludes the possibility of supplying honest days' work.

I recall, in particular, a case where I was asked to look over five claims. Sixty days' work was supposedly done on each claim, by one of these enterprising contractors. The owners had paid a ridiculously low price for the work, and they got in return a total of about thirty days' actual work distributed over all the claims. Even this total was hardly to be considered effective work since it consisted mainly in pulling moss from the rock outcroppings. Apparently this gentle exercise had grown monotonous, for the contractor appears to have found relief in a little light trenching. Needless to add that the properties were quite valueless and the owners perhaps rather innocent. The point is, that the contractor recorded the days put in and received his cheque on production of the Recording Office papers.

The instance I have cited is a particularly bad one, but there are many similar cases and it is high time the matter was looked into. The premium upon false affidavits should be removed, and the suggestions of Mr. Rennie, along these lines, are worthy of study and further elaboration. The recording of actual work would tend to systematize effort, destroy graft, and render the mere shovelling of snow non-effective.

I observe that Mr. Rennie has not given us any standards of what should constitute a day's work, but no doubt it was at the back of his mind, since the system is capable of elaboration to the point of fixing suitable, and equitable standards. Thirty days trenching, for example, may eventually be expressed as so many cubic feet and perhaps finally recorded in that way rather than as thirty days' work.

It may be objected that many prospectors are not capable of measuring up their work, and recording it in the prescribed form. The retort is, that similar plans are now required for the purpose of recording claims—the proposed requirement is no more complicated than the old.

Any valid objections that might be urged against the adoption of Mr. Rennie's proposals would probably be prompted by a fear of too great elaboration. Moderation is, of course, assumed, for it is easy to foresee that such regulations might be carried to the point of becoming a burden, and a cause of mere vexation.

It is to be conceded that the "wild-catter," and the legion of the "blanketers" and schemers would find the passing into law of Mr. Rennie's proposals very burdensome in their most simple form; it is just this fact that makes them so valuable and altogether desirable.

JOHN HANDLEY,
Mining Engineer,
New Liskeard.

From Oct. 1st, 1908, to Feb. 18th, 1909, inclusive, the Government paid the Dominion Iron and Steel Company and the Nova Scotia Steel and Coal Company sums aggregating $40,908, in bonuses on coal used in the manufacture of iron and steel in the province.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay.—The Coal Conspiracy Case.—The walking delegate from the United States must often put his tongue in his cheek and smile to himself at the complacency with which Canadians allow their country to be plundered and its peace to be disturbed by the itinerant apostles of discord sent here by the international labor unions. One of the most glaring instances of the undefended state of our industries in this regard is the so-called coal conspiracy case, in which the Grand Jury of the Supreme Court of Nova Scotia found "no bill." It is almost inconceivable that such a judicial farce could have been enacted. In Nova Scotia we are more largely dependent on the coal industry than on any other, as from it we derive much of the provincial revenue, and large industrial populations are entirely supported by it. In the best market for our coal product, namely, the St. Lawrence ports, our coal exports have to face an unrelenting competition from United States coal, which the protective duty alone enables us to meet. Simultaneously with great activity on the part of the United States coal operators in the St. Lawrence markets, there appears in Cape Breton great activity amongst emissaries of the United Mine Workers of America. This body allows a specially low rate to enable that district to send coal into Canada. The United Mine Workers then call a strike, without rhyme or reason, to embarrass the largest coal company in the province. The strike is not successful, and then the United States organization, which is doing the work of the United States coal operator, commences to prosecute the Canadian coal operator for attempting to sell his coal at too high a figure, and uses the powers of the law to compel the Canadian operator to produce in court for the edification of the world at large, and the United States sales agent in particular, his most valuable and guarded private data. The coal companies were asked to publish their mining cost sheets, and their sales price-books, their freighting costs, their profits and their correspondence. All this was done at the request, not of citizens of the province, but of alien agitators engaged in injuring the business of the men they were using the machinery of the Canadian law to prosecute. Not a tittle of evidence was adduced which proved the justice or accuracy of the information laid against the coal operators; the money to defray the legal costs of the prosecution came from the U. M. W. treasury at Indianapolis, and the whole business was evidently a vexatious persecution instituted without serious hope of success or adequate grounds, and was intended to be a lever to compel the Dominion Coal Company to abandon its prosecution of the U. M. W. leaders for libel. It is extraordinary that our courts of justice can be employed by aliens in this manner. The city of Halifax is to have the pleasure of paying witness fees amounting to some $2,00 in connection with this case. In Cape Breton it has long been recognized that the U. M. W. A. is a dangerous menace to our prosperity and progress. Eventually it may dawn upon other parts of the province that the U. M. W. A. is a nuisance, although it is probable that Halifax obtained fully two thousand dollars worth of amusement from the protracted enquete, and it is only fair that they should pay for the diversion.

The Dominion Coal Company have recently obtained a number of Ackroyd & Best's safety lamps, fitted with Messrs. Cunninghame & Cadman's asbestos attachment for detecting firedamp in mines. These lamps are of the usual magnetically locked and electrically lit type, but are of peculiar construction, inasmuch as the body of the lamp is of aluminium, while the oil attachment has been explained in the Transactions of the Institution of Mining Engineers and in the columns of the "Colliery Guardian." It consists of a small piece of asbestos blue-board, so constructed that it can be lowered on to the flame. The asbestos is treated with a solution of hydrochloric acid and soda, which gives a clear and easily defined cap in a mixture of gas and air. A perpendicular meter is attached to the asbestos graduated in tenths, by means of which the exact percentage of gas in the air can be estimated. The lamp can be used by the examiner in the ordinary way, and will give exact results without the necessity of carrying a specially constructed testing lamp such as the Pieler lamp. A great deal of attention is being devoted at the present time in England to more exact methods of testing for gas in mines, and to the construction of safety lamps.

The Workmen's Compensation Act, which has been introduced as a Government measure by the Nova Scotia Government, is not favourably viewed by the members of the Colliery Relief Societies. It is recognized that a measure like the Compensation Act, particularly the very crude draft which is now before the Nova Scotia Commons, brings with it many penalties, one of which would be the extinction of the Relief Societies and the benefits at present obtained by the miners through the operations of these self-supporting bodies. Some interesting figures have been presented to the committee which is dealing with this proposed measure as to the dissection of the disbursements of the Relief Societies. It may surprise many people to know that 54 per cent. of the benefits paid out by these societies is for sick relief, and that only 35 per cent. is disbursed for accident relief. The Relief Society gives its members protection all the time, and is in fact the miner's sheet-anchor. Probably the weakest feature of these societies is the small payment at death, but here again the Relief Society operates most beneficially where the family left is largest. The widow receives a monthly payment for one year, but for each child she receives a monthly payment until they attain a certain age, generally thirteen years. Under the operation of the Compensation Act the dependents of a man killed at work would receive a comparatively large sum in one payment, often with a disastrous result to the recipients, who are unused to the possession of much money at one time, and do not know how to use it to best advantage. The Relief Societies are supported by contributions from the workmen, the Government and the companies, and this mutuality of support and control works for the best interests of all concerned, and is an admirable check on that bugbear of the Compensation Act, namely, malingering. The accumulated funds of the Relief Societies at the mines of the Dominion Coal Company alone amount to over $45,000, but these funds are not invested to the best advantage, only earning the ordinary 3½ per cent. paid by the banks. Properly invested, these funds should bring in at least twice the amount of interest they now earn. The members of the Relief Societies do not like any interference with their independence, but it could easily be arranged that a "merger" of the general funds should take place, without interfering with the individual management of each society. The collieries are so inter-related, and their workmen move about from one mine to another in such a way, that a common fund for the reserve or surplus would net at least $1,500 per year additional interest. The conclusion arrived at by the commission which investigated the Relief Societies some time ago seems to be confirmed by the present attitude of the members, namely, that the best and most beneficial method of providing relief for the victims of accident and disease around the collieries is by an enlargement and consolidation of the present Relief Societies, which even in their present state have been probably the most powerful influence for good around the colliery villages. The Relief Societies afford relief to those who need it most and are also most deserving. They protect the miner in sickness as well as in the event of accident, while at the same time they discourage malingering. The Compensation Act, however, tends to drive the weakest to the wall, and enforces upon the employers in self-protection the necessity of dispensing with all aged or defective employees, while at the same time it puts a premium on malingering, de-

stroys the independence of the employees, and causes endless litigation.

Glace Bay.—The output of the mines of the Dominion Coal Company for March was 243,763 tons, or an average daily production of 9,370 tons. There are two new producers, namely, No. 15 and No. 6 Collieries. No. 15 is the newest mine, and is situated on the Lingan seam. No. 6 mine has not worked for about a year, owing to the pleasantries of the United Mine Workers, but during April it will become a perceptible addition to the steadily increasing total output of the company. Under the rules of civilized warfare, no blockade is recognized that is not effective. How ineffective the U. M. W. A. strike is as a blockade of the company's operations at Glace Bay may be judged from the comparative figures of monthly outputs for the first quarters of this year and last, which are as follows:—

	1909.	1910.
January	200,176	212,073
February	209,656	204,521
March	253,622	243,763
	663,454	660,357

The men employed daily at the mines alone (all subsidiary and transportation employees excluded) number 4,300. The number of men now out on strike is 1,200, about 500 men having returned to work since the strike commenced. These figures should carry their own significance. New men are arriving at the mines every day, and by the opening of navigation, barring serious accidents, the absolute failure of the strike will be apparent even to the most biased sympathizer with the U. M. W. A.

In face of the foregoing facts, it is amusing to read an interview which the local president of the U. M. W. A. gave to the Halifax Herald recently. It was gravely stated that the number of men who came out on strike last July was 5,000, of which number 2,000 had gone West, leaving 3,000 men on strike at the mines. The funny part of the matter is that the Coal Company never employed more than 5,000 men in their mines, and that the number of men belonging to the Provincial Workmen's Association who remained at work at the time the strike was called outnumbered the strikers by two to one. It is a little late in the day for the leaders of the U. M. W. A. to rehash all their stock misrepresentations, but there seems no limit to their mendacity. At one time, before the public were properly informed, there was some purpose to be served by their lies, but to-day, when the general untruthfulness of these men has been exposed, it is but foolishness on their part to persist further, as it merely serves to confirm the public in their suspicions that the U. M. W. A. is an untruthful organization, and that its officers will stick at no amount of misrepresentation to serve their own ends.

ONTARIO.

Cobalt.—The majority of cases against the Cobalt high graders have been held over till May, when those implicated will again come up for trial. The information in all of the charges has been changed, so that now the defendants are charged with having ore in their possession which is the legal property of the Crown. This is to conform to the statute that declares that any ore for which an owner cannot be found lays in the name of the King. By this means it is hoped to get around the old law, which throws the onus of proof of ownership on the complainant.

A few days ago the ore-house at the Trethewey Mine was broken into and 200 pounds of nuggets, valued at approximately $1,000 was stolen. So far, no trace has been found of the stolen ore.

The new mill at the Silver Cliff is now ready to run, and all the machinery has been turned over, and is in good working order. It is estimated that there are about 18,000 tons of ore on the dumps and in the stopes. The work done below tunnel level has proved up the veins, to a depth of at least sixty feet, and the values in the bottoms of the workings are very encouraging.

Work has been resumed on the Silver Lode property, which lies to the east of Cross Lake. A new shaft-house is being built, and as soon as power can be obtained the shaft, which is at present down 120 feet, will be sunk to greater depth. There is a vein of calcite and cobalt showing in the bottom of the working.

Good ore is now being obtained from the new shoot opened up on the Ophir property. The vein shows about eight inches of calcite and smaltite, and carries some native silver.

The Nipissing has declared the regular dividend of 5 per cent., with a 2½ per cent. bonus, payable April 20th, to shareholders of record April 1st. The La Rose has also declared a 2 per cent. dividend, payable April 20th. Up to date for the present year Cobalt companies have paid and declared dividends amounting to $2,324,527. This does not include the profits returned to the owners of the private corporations, the O'Brien and the Drummond. During the month of April six companies will disemburse to their shareholders dividends amounting to $970,293. The companies that have declared dividends for the present year are as follows:—

Nipissing	15%	$900,000
Crown Reserve	30%	530,644
Kerr Lake	10%	300,000
La Rose	4%	300,000
Buffalo	8%	80,000
McKinley-Darragh	5%	112,346
T. & H. B.	600%	46,566
Right of Way	2%	29,971
Haileybury Silver	50%	25,000
		$2,324,527

The Haileybury Silver is paying the dividend out of money raised by the sale of the south half of its property to the Haileybury Frontier Company. This latter company recently struck high-grade silver ore on the 65-foot level on what is supposed to be a continuation of the Keeley vein.

The famous Cobalt Gem nugget has been purchased by the Ontario Government for the sum of $5,054. This nugget, which is the largest piece of float ever found in this district, was discovered on the property of the Cobalt Gem Mining Company, a Philadelphia organization, and with the exception of a few small pieces of float, constitutes all the ore that has been taken from the claim. The nugget weighed 1,640 pounds, ,and was 40.62 per cent. pure silver, containing 9,715 ounces. It now forms part of the collection of the Bureau of Mines at Toronto.

The Lewisohns, who control the Kerr Lake Mine in Cobalt, have made the second payment on their option of the Wettlaufer Mine in South Lorrain, thus giving them the control of this property. The Wettlaufer is the best known and most important property in the South Lorrain district, and has been the bonanza mine of that camp, having had high grade ore from the grass roots down. Since the Lewisohns took an option on the property, development work has been pushed, and the results obtained were most satisfactory. The ore on the lower levels was found to be fully as rich as nearer the surface. Although several shipments have been made, no stoping has been done, all the ore having come from development work. The mine is equipped with an up-to-date plant, but it has been found insufficient to carry on the work, so a new twelve-drill power-driven compressor has been ordered. The Mines Power Company will have power in there some time this summer.

The Hargraves Mine has entered the list of shippers, having sent out 21 tons of high-grade ore. This is the first time this company has shipped since it was reorganized. In the early days of the camp one 28-ton car was shipped with ore taken from the surface.

As the winter roads into Elk Lake are now impassible, it is probable that there will be no more shipments made from Gowganda until next winter. The tonnage that came from there is in

excess of what was estimated, and the shipments were also exceedingly high grade. As was expected, the Blackburn or Millerett was the heaviest producer, sending seven cars, containing an aggregate of 198 tons. The Reeves-Dobie shipped 62 tons, the Boyd-Gordon 30 tons, the Miller Lake O'Brien 11 tons, the Welsh 1¼ tons, and the Burke-Remey 2 tons, the two latter being sample shipments. The amount of ore that has come from this district is very creditable, considering the difficulties under which mining operations are carried on, and has done much to restore public confidence in the future of the camp. A new discovery has been made at the Boyd-Gordon, and the ore is reported to be almost pure silver. The Bishop Mine has four veins showing silver and an ore shoot carrying about 1,000 ounces has been opened up at a depth of 70 feet. S. D. Epplet has found a vein carrying good values in silver on one of his properties near Hanging Stone Lake. He now has 40 men working on the different claims. As a whole, the district is looking better than formerly, and all indications point to a renewal of activity this summer. At present things are hung up on account of the early break-up, and it is stated that there are nearly fifty cars of supplies of various kinds at Charlton that it will be impossible to send in.

The Elk Lake district has also helped to swell the list of shippers, the Lucky Godfrey having sent out a twenty-ton car of high grade ore. This camp has suffered in comparison with Cobalt and Gowganda, but has notwithstanding made a very good showing. There are practically a dozen mines in that section that have pay ore, and as they will be more actively developed than formerly, better results may be expected.

The Large property, situated on Cross Lake, which has been in litigation for two years, was purchased by the Valentine Mines, Limited, immediately upon the settlement of the case in the courts. As soon as sufficient money is raised by the sale of stock, development work will be started.

The T. & H. B. has declared another dividend of 300 per cent., or $3.00 per share, this making the third dividend for 1910. When this last dividend is paid, the company will have disembursed to its shareholders $160.00 per one dollar par value share in dividends.

The City of Cobalt is now having its dump treated at the rate of 50 tons of ore a day, and it is estimated that there are about 14,000 tons available. The Northern Customs Concentrator, which has the contract for milling the ore, is now running by electric power throughout.

The long-heralded compressed air has at last reached Cobalt, the Mines Power Company having begun giving commercial service on April 4th. There had been air in the pipes at different times for a week before that date, but the service was not continuous. They are also supplying electric power, and several plants are now in operation. A good many other plants will be using this same air and electricity in a few days, because a number of mining companies would not sign a contract for their supply until they saw which power company was first in the field. The Hydraulic Power Company is rapidly getting in shape to turn the water down the shafts. There is, however, a certain amount of work to be done, and it is hard to say just when they will be ready to deliver air. The Cobalt Power Company is giving electric energy to some plants, but this is from a unit that has been installed at Ragged Chutes, at the plant of the Hydraulic Company. Their main plant will soon be ready, as they are now installing the last of the machinery.

Porcupine.—The early break-up of the winter has caused consternation in many parts of the district, because as it was not expected for about a month, many companies will now be unable to get in their supplies. The roads are now impassible for teams, and men going in or coming out have to do so on foot. Fortunately the principal operating companies managed to get in the greater part of their supplies and machinery. The biggest deal that has yet been made in Porcupine claims was consummated a short time ago, when the famous Wilson and Edwards properties passed into the hands of a syndicate of which Mr. A. Montell is the head. Some of the people who are heavily interested in the Buffalo Mine in Cobalt belong to this syndicate. The original Wilson claim is generally conceded to have the most sensational showings of free gold of any in the district, but so far practically no work has been done on it. The owners received many flattering offers, but did not seem at all anxious to dispose of their claims until Mr. Montell's syndicate entered the field. A complete plant, including two 60-horsepower boilers and a six-drill compressor, was ordered, and it is understood is now on the property. As the roads were getting in very bad shape, a special train with fifteen teams was sent up from Cobalt to help rush the supplies in. There were, all told, about seventeen carloads of supplies and machinery, and a large gang of men is at work. In order to test the values on the surface, shots were put in in different places, and with one or two exceptions, all the broken rock showed free gold. The Scottish Ontario Gold Company are installing machinery, which they expect to have running soon. Their shaft is now down about 35 feet, and the values in the bottom are exceptionally good. The ore is being carefully sampled, and the samples sent to Scotland to be tested in the company's laboratories. The Higginson veteran claim has been purchased by a New York syndicate, and a gang of men is being sent in to open it up. Machinery will be installed later, as it was impossible to get it in before the break-up. The Timmins have their buildings up and are installing the plant, which includes a six-drill compressor. They have sunk two shafts, one of which is down 60 feet, and has free gold in the bottom. They are also getting more sulphides with depth. A sample car has been shipped from this property to a mill in New Jersey, in order to have a test run made. Care has been taken to make the car as representative as possible. The Crown Chartered Company, which purchased the Reamsbottom claims, has part of its plant on the ground. They are putting up a small sawmill, and expect to cut lumber for other concerns as well as their own. The Foley-O'Brien properties are looking well, and free gold has been struck at the bottom of the shaft. They are operating on the Wright and Forneri claims, and also have a veteran claim near the south end of Porcupine Lake. During the coming summer there will be three compressors in operation and probably six plants. When these are working it will be possible to sink the shafts to greater depth, which is, of course, necessary to determine the extent of the deposits. Arrangements have been made to run a line of boats on the lakes as soon as the ice is gone, which will be a great aid to transportation in the summer months. The greatest need, however, at the present time is for a summer road. The Government has been petitioned to build this, but so far has shown no decided inclination to carry it out. Several roads are projected, but these are as yet up in the air.

GENERAL MINING NEWS.

NOVA SCOTIA.

North Sydney, April 5.—The Nova Scotia Steel Company's steamer Wobun sailed from North Sydney on April 5th for Montreal with 2,450 tons of coal. The Wobun is the first coal steamer to go up the St. Lawrence this season.

The steamer Kronprinz Olav, Captain Neilson, sailed yesterday afternoon from the Dominion Coal Company's pier, coal laden, for Montreal. The Kronprinz will be the first ship to sail up the river with coal cargo from the Dominion Coal Company for 1910.

Halifax, N.S., April 8.—The bill to amend the Nova Scotia Steel Company's charter passed the Legislative Council yesterday with the directors' residential clause eliminated, and was sent down to the House of Assembly last night in that form.

This morning the House Committee gave a hearing on the bill and was addressed by Mr. H. A. Lovett, K.C., representing the upper provincial interest, and Mr. Mellish, K.C., and Mr. Cantley, of the Scotia directorate, in favour of the bill.

Mr. Lovett urged that shareholders who invested money in stock on the face of the charter had rights and interests to be considered. There was no necessity of an amendment to permit an increase of capital. The company now has one and a half million in bonds, so an increase could be of no immediate necessity, and, if so, the shareholders' wishes can be learned at ten days' notice. He claimed that the clause would be capable of becoming effective for other purposes. Any directors wishing to retain office could, the day before the annual meeting, count up the list and if things did not look favourable, create three millions of new capital and subscribe for it themselves or have friends do so, and thus it could be voted on at the meeting.

Mr. Mellish submitted that it was not a general practice in the Legislature to restrict an issue of additional stock in the manner suggested, as statutes showed. Nor was it the general policy to restrict the power to issue new stock to majority shareholders. The chairman of the committee asked if the present directors were unanimous in favour of the bill. Mr. Lovett said some were not.

Hon. Mr. Rogers said that under the by-laws it was not necessary to notify those outside the province of meetings to be held. The concern has been managed by resident directors.

Mr. Lovett said that under the by-law recently made, no matter how many directors reside outside the province, the president can call a meeting without notice. Four is then a quorum and could authorize the introduction of a bill.

Mr. Cantley said in regard to a quorum that the question of the by-law was not a recent one. Directors in the province were all in favour of the act. The management of the concern had been left entirely to the efforts of those directors.

Reference has been made to outside interests in the company. At the recent New Glasgow meeting the present management had the support of 27,830 votes, representing 537 shareholders; the opposition had 9,480 shares, representing 75 holders. Allowing them six shareholders in dispute, they had 81 as against 537. The province is vitally interested in underlying securities. At this moment the province holds 85 per cent. of debentures and $2,750,000 of bonds. Upper Canada took $700,000 out of $3,500,000 bonds. When the first bond issue was made the company looked to Nova Scotia for money and was not disappointed.

Halifax, N.S., April 1.—In the Supreme Court to-day in the action brought by the U. M. W. A. against Messrs. J. R. Cowans and Alex. Dick, charged with conspiracy, the Grand Jury reported no bill, thus ending the coal conspiracy cases.

ONTARIO.

Cobalt, April 7.—After many vexatious delays the Government have at last signed the royalty reduction agreement with the Chambers-Ferland. All the other reductions concerned companies paying tribute to the T. and N. O., and they have been ratified a long while ago. The Chambers-Ferland pay direct to the Ontario Government. The old royalty was on ore at the pit's mouth, 25 per cent, of the output, the new rate is 25 per cent on the profits.

ALBERTA.

Lethbridge, April 7.—J. N. Greenshields, of Montreal, has purchased the controlling interests in the Lethbridge collieries. The original owners, among whom were Hon. Colin Campbell, of Winnipeg; Jos. Griffin, of St. Thomas, Ont.; Isaac Cockburn, of Winnipeg, and the late George Rogers, of Lethbridge, will retain their interests. It is understood that the Grand Trunk Pacific is behind the deal, and will spend $400,000 in development.

BRITISH COLUMBIA.

Fernie, B. C. April 2.—The general strike ordered in the bituminous coal districts in the United States is not liable to cause any disturbance among the miners of the Crow's Nest District or Southern Alberta coal field. Neither the mine workers' officials nor those of the coal companies are looking for more trouble here. The year's agreements which were entered into a year ago have been giving general satisfaction, while in those camps where no agreements have been arrived at the feeling is mutually conciliatory and in no place is there any friction of consequence.

At Frank, where the Canadian Coal and Coke Company operates, the agreement expired yesterday, and the men are out as a result of the company refusing to discuss a new agreement, except on conditions that a reduction of five cents per ton be allowed on pillar work, together with the discontinuance of the closed shop principle, and that the jurisdiction of the United Mine Workers of America is not to include men working in and around the shaft house. There are from 175 to 200 men involved in the dispute.

The output of the Crow's Nest Company's mines for the month of March made another record, totalling 112,000 tons, the first time in its history when the hundred thousand mark was passed. The same conditions prevail at all the camps and the demand is always for more.

The total tonnage for the district from Taber to Fernie is now fully 10,000 tons per day, the Fernie mines furnishing fully one-quarter of the amount.

Rossland, B. C.,—A second strike has been made in the War Eagle mine at Rossland, B. C., now the property of the Canadian Consolidated company. Like the last it is an entirely new ore body, hundreds of feet north of the War Eagle vein proper, and like it, too, is exceedingly rich.

The first big strike was made about a year ago in a crosscut 500 feet to the north from the 11th level, 1650 feet from the collar to the shaft. The ore shoot then found has been tapped on both the ninth and tenth levels, and has been found so far to have a height of 375 feet, a length of 400, and a width approximating 50. Aside from its size, its most notable feature is the high grade of ore it contains, shipments for months past having averaged $40 per ton in gold, and about four per cent copper, much higher values than were ever obtained for a similar tonnage from either LeRoi or War Eagle mine during the days of bonanza production.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

Early reports of the mineral production of the United Kingdom show that the coal output for last year was 263,758,562 tons, as compared with 261,512,214 tons during the previous year. Oil shale figures went up from 2,891,564 tons to 2,966,937 tons; iron ore output stood at 9,713,284 tons; black tin ore at 7,381 tons of dressed ore. Ores of copper declined to 3,678 tons; lead ore increased slightly, showing an output of 29,688

tons; zinc ore dropped almost 40 per cent., returns showing an output of 9,902 tons. Tungsten ores increased to 368 tons, the previous year's output being only 229 tons. Arsenic increased from 1,919 tons to 2,865 tons.

The Miners' Conference resumed its sitting in London on March 30th, for the further consideration of the proposals for the settlement of the South Wales dispute. Mr. Enoch Edwards, M. P., again presided over the 150 delegates present, and Mr. Isaac Mitchell, of the Board of Trade Labor Department, also attended.

The employers had stipulated that a definite answer should be given to their proposals before noon on March 30, and in case the reply was favorable contracts were to be continued from day to day until 9th April, in order to allow a ballot to be taken.

The conference sat for nearly four hours, and at the end the official report stated that the following proposition was submitted to the conference on behalf of the Executive Council:—

"After having carefully considered the whole position in South Wales, we strongly urge the conference to advise the workmen to accept the terms of settlement put before the conference as the outcome of the negotiations between the coal owners and the miners' representatives,, as we do not think the points of difference are sufficient to justify either a sectional strike in South Wales or a national struggle, with all the tremendous issues involved. This not to be taken as committing other districts of this federation to support an amendment of the Eight Hours Act."

A long discussion ensued upon this being proposed and seconded on behalf of the council, in which representatives from nearly all the districts in Great Britain took part, after which the resolution was carried.

Mr. T. Richards, M. P., in the course of an interview, stated that the owners had agreed not to press the clause with regard to abnormal places, but were prepared to leave matters as they stood at present on condition that the rest of the proposals were agreed to.

Mr. Alfred Onions, one of the leaders of the South Wales miners, stated that it was now the intention to take the ballot of the miners immediately. This ballot, he said, will be confined to the workmen in the South Wales coal fields.

AUSTRIA

A special report furnished from Vienna to the "Frankfurter Zeitung" sets the position of the Galacian oil industry in a very unfavorable light, and in fact points to the tactics of the Standard Oil Company in that country having been crowned with so full a measure of success that the very existence of the home industry is seriously threatened.

"The Austrian petroleum industry," says the writer of this report, "is to-day literally fighting for its very existence. While the Vienna Bourse has been dreaming of an understanding being come to, not merely within the ranks of the home industry, but also between the groups contesting the pre-eminence in the world's markets, competition has become more acute than at any previous date. The Standard Oil Company has gradually depressed both wholesale and retail prices in Germany to such a low level that the Austrian export refineries are only getting an average price of 3¾ marks,, as compared with 5 or 6 marks of a year or two ago. At the same time, in Austria, the Vacuum Oil Company and the refineries attached to it are attracting buyers more and more by offering their product at prices entailing a loss at present prices of crude oil, which is appraised at just the same value as the finished product. The Vacuum Oil Company is now in a position to meet about 20 per cent. of the Austrian consumption of petroleum. Allied with it is the French refinery in Limanova, and it is becoming more probable every day that the "Austria," also with its refineries in Mahrisch-Schonberg and Drohobycz, is also controlled by the Standard Oil Company.

"It is not believed that the 'Austria,' which is not very strongly capitalized, could afford to lose 2 to 3 kronen per cwt. on the refined oil it is selling—as both it and the Vacuum Oil Company are actually doing—unless it had the Standard Oil Company at its back."

"Already," continues the report, "some of the large refineries have considerably reduced the number of their hands, and this gives colour to the statement made recently that the Austrian oil export trade would be now restricted on a systematic plan. Of course, refineries and plant generally had been erected on a scale to facilitate the largest possible export, but now, in view of the continued policy of depressing prices both for oil and all bye-products indulged in by the Standard Oil Co., increased exports only mean increased losses. This development shows how short-sighted was the policy of the Austrian Government, which was entirely based upon a rise in prices. It has only been playing the game of the Standard Oil Company, which on account of its boundless pecuniary resources can sacrifice millions for a series of years with equanimity if it can thereby either drive the Austrian petroleum industry from the international market or make it merely a vassal of its own. It is suspected that an alliance of the various oil districts in the European Petroleum Union against the Standard Oil Company is under discussion, and this may be joined up with the establishment of a Government monopoly in Germany. All this, however, can only be a long way off, and at the present moment the actual situation and the prospects of the Galician oil industry are perhaps the most unfavourable yet recorded in its annals, which have been rich enough in critical occurrences."

SOUTH AFRICA.

Johannesburg.—Mr. J. G. Hamilton, presiding at a recent meeting of the Chamber of Mines, said that the State Mining School would be discontinued, and instead of it fifty youths, under ordinary contract conditions, would shortly be instructed at the Wolhuter mine under State supervision. The chairman remarked on the improvement in the supply of native labour, and stated that February's recruiting was a record. He announced that a miners' phthisis sanatorium would be established immediately.

Johannesburg.—Strenuous endeavours are being made by the principal members to continue the existence of the Transvaal Coal Owners' Association in order to prevent serious price-cutting and the disappearance of profitable operations. In order to allow of further negotiations to that end the placing of the contracts for the supply of coal to the Eckstein group of mines has been postponed for a week.

Speeches at recent company meetings have been chiefly noteworthy for disclosures of further record schemes of development and announcements of large increases in the tonnages to be milled. On the Simmer Deep crushing is to be increased to 72,000 tons monthly, its ore reserves totalling 1,300,000 tons worth 5.2 dwts. The Jupiter crushing is to be increased to 48,000 tons monthly, the ore reserves totalling 1,215,000 tons worth 6 dwts. Knight Central's crushing is to be increased to £90,000 in hand. The Geduld Proprietary expect to raise the monthly crushing to 17,000 tons.

The crushing by the Vesta mill, on the Black Reef, has resulted in a recovery of 8 dwts. per ton, whilst the resulting sands and slimes are expected to produce other 4 dwts. The management express themselves as highly satisfied with these figures.

Natal.

The output of coal from the Natal collieries during the year 1909 amounted to 1,786,583 tons—the highest figures reached since the start of the industry. In the year 1889 the output was only 25,609 tons and in 1908 the amount mined was 1,669,774 tons. During 1909 vessels replenished their coal bunkers at Durban to the extent of 835,496 tons, while 404,322 tons were exported from Durban by sea. The output for January last forms another record, the amount being 192,145 tons. Durban is

rapidly establishing itself as one of the leading coaling ports of the world, and additional rolling stock has been forwarded to the colony to meet the growing requirements of the port.

UNITED STATES.

Nederland, Col., April 8.—The activity among tungsten miners will be augmented by the recent rise of 50 cents per unit and the fact that the output of the past few months has at last attracted the attention of General Manager Hayes, of the Denver, Boulder & Western road, who has submitted plans to run the road from the Sulphide spur into town, to be put into operation within 30 days.

While mine owners generally assert they cannot operate their own properties to advantage at less than $11 per unit, leasers are doing well.

Marquette, Mich.—The great ore fleet is beginning to fit out for the year's work. The vessel owners have a big job to do, and are bestirring themselves. They plan to move 50,000,000 tons of ore before the ice again locks up the lakes. This is by all odds the biggest contract the lake carriers have ever undertaken, and the big fleet of ore-carrying ships will soon be in trim to start on it. It must be accomplished between the middle of April and the first of next December—seven months' time—so there are no days to be wasted.

In Marquette and at every port on the lakes there will soon be bustle on the decks and in the holds of the ore carriers. The first motion was noticeable in the local harbour fully two weeks ago, when the advance guard of men arrived and began the work of fitting out the Pathfinder and Warner, which have laid in the horbour all winter. Additional arrivals since have swelled the crews. Those now at work are connected with the engineering department of the ships, and some of the superior officers. They are overhauling the machinery, making other minor repairs, and thoroughly examining the vessels so there will be no hitch when they are about to take on their first cargo.

It is the intention to have these boats ready in time to be loaded and start out as soon as the insurance takes effect, April 15. The ships at the lower lake ports and at the head of the lakes are also getting ready, and will be waiting at the Soo locks prepared to pass through as soon as they are given opportunity.

The ore fleet numbers between 200 and 300 big ships, owned by the Steel Corporation, the Cleveland Cliffs Iron Company and several other companies and individuals. The Steel Corporation owns 102 of these vessels, and is the heaviest ship owner in the world, as well as the largest owner of iron mines and iron works.

Goldfield, Nev., April 4.—Preliminary estimates, issued Saturday afternoon by Manager Finlay of the Goldfield Consolidated the gross value of the ore at $1,015,000. The recovery value is Mines Company, bearing upon the production for March, places placed at $950,000, and the net profits at $730,000. During the month the mill treated 26,717 tons, thus establishing a new record. It will be recalled that March a year ago was the heaviest month of that period.

The annual report of President Lockhart of the Goldfield Florence Mining Company, accompaning the dividend checks just mailed shows the last year's profits to have been $232,050. The company paid two dividends totalling $210,000.

COMPANY NOTES.

DOMINION COAL COMPANY, LIMITED.

Report of the Board of Directors to be Submitted at the Annual General Meeting of the Shareholders on the 12th April, 1910.

To the Shareholders of the Dominion Coal Company, Limited:

Your Directors submit herewith a statement of the affairs of the company as at 31st December, 1909, and of the earnings of the year then closed.

The year opened with great promise, but early in July a strike was called by the United Mine Workers' Association, an American organization which had recently sought to establish itself in Nova Scotia; the object of the strike being to obtain recognition. The refusal of your Directors to grant this was sustained by a Board of Conciliation held under the Lemieux Act.

A large proportion of the company's employees were members of the provincial organization, and these, with many others, have remained steadily at work. The reduction of output consequent on the strike, the increased cost of mining, and the direct expenses incurred for police protection, etc., all had a serious effect on the company's earnings for the latter half of the year, but the output is now nearly normal, and it is hoped that the additions which are being weekly made to the company's working force will place its operations on their usual level by the opening of navigation.

The output of the collieries for the year 1909 amounted to 2,734,774 tons, as compared with 3,555,068 tons in 1908.

Collieries: Plant.—Your Directors are pleased to be able to report that, notwithstanding the disturbances caused by the strike, the collieries are in good condition. Development work is still well in advance of mining operations, and the plant and machinery throughout have been well maintained. The new collieries in the Lingan district are being steadily pressed forward to completion, and full mining operations are now in progress at No. 12.

Sydney and Louisburg Railway.—Your Directors have caused application to be made for an Act to incorporate a railway company, to which the valuable railway property belonging to and now directly operated by the company, may be transferred. Your Directors are of opinion that this railway can be more successfully carried on by an independent company operating under the railway laws of the province, and will ask you to sanction an arrangement which, while retaining full control in the hands of your company, will place this part of your business on an independent basis.

Relations with Dominion Iron & Steel Co., Ltd.—The arrangement proposed by your Directors for a settlement of the matters in dispute with the Steel Company, mentioned in the last Annual Report, was duly carried out. The contract of October 20th, 1903, has been reinstated, the excess cost of coal received under the temporary contract repaid, and within the last few weeks a friendly settlement was reached as to all other matters in dispute between the two companies. The balance at credit of Profit and Loss Account, which was largely created by the payments from the Steel Company, was drawn on for this settlement, as appears from the accompanying statements.

Negotiations respecting the new price of coal are proceeding satisfactorily. The cost of mining and delivering coal, during the periods which govern in fixing the new price, has been ascertained by Messrs. Marwick, Mitchell & Co. on behalf of your company, and their figures are now under examination by the Steel Company's accountants.

Proposed Merger with Steel Company.—It is understood that a plan to unite the interests of the shareholders of the Coal and Steel Companies is under consideration, and will shortly be submitted to their respective representatives. Your Directors will

promptly consider and report to you on any scheme that may be placed before them.

Changes in the Board.—In December last the President, Mr. James Ross, sold 50,000 shares of the common stock of your company, which were acquired by the Dominion Iron & Steel Company, Limited. Mr. Ross subsequently resigned as President and Director, and at the same time Messrs. R. B. Angus and Graham Fraser retired from the Board.

Mr. J. H. Plummer, the Honourable L. J. Forget and Sir Henry M. Pellatt were elected Directors in their stead, the first named becoming President in place of Mr. Ross.

Of the other members of the Board, Mr. W. B. Ross, K.C., and Mr. J. Kerr Osborne, having sold their shares in the company, have ceased to be Directors, but their places have not been filled.

Management and Staff.—In January, 1910, Mr. G. H. Duggan, 2nd Vice-President and General Manager, resigned his office, and Mr. M. J. Butler, C.M.G., was appointed in his stead. Mr. John Mackay, Secretary and Treasurer, also retired from the service of the company, and Mr. C. S. Cameron was appointed to both these offices. Mr. D. H. McDougall was added to the staff as Assistant General Manager, with special charge of the practical work of the company. All these officers reside in Cape Breton.

Mr. F. L. Wanklyn having accepted an important public office, will be no longer available for the duties he has hitherto performed, but the changes made in the administration of the company's affairs will enable your Directors to divide his duties among the other officers.

Your Directors have pleasure in bearing testimony to the zeal and energy with which the general staff of the company have performed their duties during a trying year, and in expressing their confident belief that the shareholders may look for continued loyal and efficient service from the company's officers and employees under the new management of its affairs.

On behalf of the Board of Directors,
J. H. PLUMMER, President.

Montreal, April 4th, 1910.

Profit and Loss Account for the Year Ending 31st Dec., 1909.

NOVA SCOTIA STEEL & COAL COMPANY—PRESIDENT'S ANNUAL REPORT OF PROGRESS.

"In moving the adoption of the report of the directors and of the accounts which have been laid before you, I wish to avail myself of the opportunity to make a few remarks upon the business of the company. Throughout the greater part of the year 1909 the iron and steel business was anything but satisfactory, looked at from the standpoint of the shareholders. Prices in many cases with us were lower than they have been at any time during the past twenty-five years. Fortunately during the last quarter there was some improvement, which, I am pleased to say, still continues.

"The shareholders may, I think, congratulate themselves upon the fact that the profits of the year have amounted to $907,949. This is a large sum to make in a year such as I have spoken of, and it has required the greatest care and foresight on the part of the management and our official staff to produce this satisfactory result.

"In this connection I want to say that I think we are particularly fortunate in having such a careful and competent man as Mr. Cantley in charge as general manager, and also fortunate in having under him a competent staff working harmoniously for the best interests of the shareholders. It is perhaps opportune that I should at this time call your attention to the growth of this company during the past five years.

"I became president of the company in March, 1905, and all of the present board (with two exceptions, were then directors. In the previous year, 1904, the earnings were $501,337.24. For 1909 they were $907,949, an increase of over 50 per cent. In 1904 we mined and shipped from Wabana 246,022 tons of ore, and in 1909, 460,387 tons, an increase of 67 per cent. In 1904 the total coal raised at Sydney mines was 476,521 tons, and in 1909, 613,000 tons, an increase of 70 per cent. In 1910 we expect an output of 900,000 tons, an increase of 423,459 tons over 1904, equal to 88 per cent. In 1904 the output of pig-iron was 31,567 tons; in 1909 it was 58,676 tons, or an increase of 85 per cent.

"In 1904 the open hearth plant produced 30,000 tons of ingots; in 1909 the output was 64,240 tons, an increase of 114 per cent. In 1904 our cogging mill rolled 30,223 tons of ingots; in 1909 the output was 64,240 tons, an increase of 114 per cent. In 1904, our finishing mills and forge department made and shipped 25,958 tons; in 1909 the product was 56,515 tons, an increase of 126 per cent. During this period we acquired the submarine iron ore deposits at Wabana and very extensive coal areas, and have largely developed the iron ore areas. The acquisition of the submarine iron ore and coal areas and the development of the iron ore property have added many millions to the assets of the company, which do not show in our statement of assets because we have only added the bare actual cost of the areas and the amount actually spent in their development. From two collieries in 1904 we have now five well equipped, and we are well prepared to look after the expanding coal trade of the company. We have erected a new forge at New Glasgow, and have also greatly increased the capacity and efficiency of our mills there. From an output in 1904 of 30,223 tons to 52,931 tons in 1909 is a large increase, and further extensions now being made are expected to give us next year an output of, say, 70,000. When it is considered that during all the period under review the company suffered from insufficient working capital, and that all the property I have spoken of was acquired and the extensions and betterments of plants were effected without any new capital available, I think the board can properly claim some credit for having carefully, wisely and successfully administered the property committed to their hands by the shareholders. As the accounts show, our finances are in a very satisfactory condition. I am, however, pleased to be able to tell you that since the report was distributed, we have disposed of a further $1,500,000 of our bonds in London on favourable terms, and we have now ample funds on hand to provide for all improvements and extensions to our plant at New Glasgow, Wabana and Sydney Mines, contemplated for some years, and have, as well, ample working capital, for the company, as regarded from a financial point of view or from the standpoint of its physical condition, was never better than it is at the present time.

"The remaining $1,000,000 of bonds the directors consider it unnecessary to sell, as the money is not now required. In addition to this $1,000,000 of bonds in the treasury, we have power to dispose of $6,000,000 of debenture stock if and when it is required for future developments or extensions or other purposes of the company. During the past few years when we were developing our coal and iron areas we were handicapped by not having any securities in the treasury which could be issued to provide for such capital expenditure. Having experienced this difficulty, your directors determined when reorganizing the finances of the company that ample provision should be made for its future requirements. The importance of this cannot be over-estimated. Another very gratifying feature of our report is the fact that we have not added one dollar to our property account by reason of the premiums paid on the redemption of our old bond issues nor the discount on the sale of the 3,500,000 of debenture stock disposed of and referred to in the report.

"The substitution of the new 5 per cent. fifty-year bonds with a sinking fund of one-half per cent., in place of the previous bond issues upon which we were paying 6 per cent. interest and 2 per cent. sinking fund, will effect a large saving in interest has given us a large capital for further developments of our property and provided us with ample working capital, and, notwithstanding the additional capital thus secured, our fixed charges will not be materially increased. In 1904 the company sold its consolidated 6 per cent. bonds at 87½ per cent. of par, so that the company then paid interest at the rate of 6.86 per cent. for its money. In 1904 our 5 per cent. fifty-year bonds realized 94 per cent. of par, making our interest rate 5.32 per cent., or a little over 1½ per cent. less than on the loan made in 1904. You are all aware that during the year we issued to our shareholders a stock bonus of 20 per cent., thus compensating for the dividends which we considered it unwise to pay out during the years when we were using so large a proportion of our earnings for capital expenditure.

"I feel that you are to be congratulated on the improved financial condition of the company, and the prospects for the future. There has been a marked improvement in the iron and steel business in Canada, and unless something unforeseen happens, we believe that 1910 will be the best year in the company's history. The development of the submarine iron ore properties at Wabana has verified our expectations in regard to it, and there is no longer any doubt as to the enormous value of the areas.

"With regard to the important question of future dividends on the common stock of the company, I can see no reason, in view of the present financial position of the company and the power we possess to issue securities to provide for any extensions of our business, why a reasonable proportion of the earnings of each year should not be paid to the common shareholders.

"The board have already declared a dividend of 1 per cent. for the first quarter, and if the earnings of the company for the balance of the year prove to be as large as they now promise I think a substantial increase should be made before the end of the year to the present rate of dividends on the common stock. I do not think there are any other matters in the report which call for further remarks from me at this time, and I therefore move the adoption of the report and financial statements."

NIPISSING ANNUAL.

The annual meeting of the Nipissing Mines Company will be held in Augusta, Me., on April 25th, at 2 p.m.

On April 1st the Buffalo paid 5 per cent. to its shareholders and will pay a bonus of 3 per cent. on May 16th. These disbursements will make total return to shareholders of 73 per cent. of the capital stock.

DOMINION IRON AND STEEL.

The output of the Dominion Iron & Steel Company for the month of March was very heavy, and the shipments also were heavy for that month.

The March figures follow:—

	Tons.
Pigs	22,320
Ingots	25,809
Blooms	22,870
Rails	13,680
Rods	7,730
Shipments	25,180

STATISTICS AND RETURNS

STATISTICS AND RETURNS.

The shipments of the Hill Crest Coal & Coke Company for March amounted to over 16,000 tons. Mr. Brown, the new manager, is on the way to take charge of the property.

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending April 8, and those from January 1, 1910, to date:—

	April 8. Ore in lbs.	Since Jan. 1. Ore in lbs.
Buffalo	52,900	522,528
City of Cobalt	.....	300,445
Chambers-Ferland	.....	58,000
Cobalt Central	.....	295,186
Cobalt Lake	.....	132,000
Colonial	43,000	107,260
Coniagas	.....	434,096
Crown Reserve	62,500	1,507,570
Drummond	.....	664,200
Hargraves	.....	41,800
Hudson Bay	.....	123,695
Kerr Lake	240,190	1,919,079
King Edward	.....	134,506
La Rose	146,400	2,147,570
McKinley-Darragh	.....	725,441
Nipissing	252,817	2,953,004
O'Brien	61,700	453,006

Ore shipments for week ending April 8 were 982,958 pounds, or 491 tons.

Total shipments from Jan. 1 to April 8 were 15,066,984 pounds, or 7,533 tons.

The total shipments for 1909 were 30,098 tons.

TRAIL SMELTER.

The Consolidated Mining & Smelting Company of Canada, Limited, report ore receipts at Trail Smelter for week ending April 2nd and year to date, in tons, as follows:—

Company's mines—		
Centre Star	4,775	50,198
St. Eugene (concentrates)	128	4,775
Snowshoe	3,298	49,676
Richmond-Eureka	58	1,278
Sullivan	108	2,270
Other mines	1,257	23,554
Total	9,624	131,751

B. C. ORE SHIPMENTS.

The ore shipments for week ending March 26th are slightly below the average this week owing to decline in tonnage from the Granby mines. Appended are the details:—

Boundary.

	Week.	Year.
Granby	23,582	308,838
Mother Lode	8,000	106,805
Oro Denoro	360	3,480
Snowshoe	3,240	46,378
Wellington	.....	11
Other mines	11	152
Total	35,193	465,664

Rossland.

Total	41,501	541,368

MARKET NOTES.

New York, April 8.—The foreign visible supply of copper during March showed a falling off, the decreases totalling 4,524,000 pounds, making the foreign visible as of April 1, 249,625,600 pounds. For the preceding 10 consecutive months the visible supply increased monthly, beginning at 114,068,800 pounds, as of May 1, 1909, and reaching the high mark of 254,150,400 pounds at the end of February.

The decrease in the foreign visible permits of an increase in the United States stock for March of 4,500,000 pounds without

changing the statistical position of the market.

Exports for March were larger than the earlier government figures indicated, totalling 43,771,840 pounds. It is expected that the producers' statistics for March will show at least 45,000,000 pounds shipped to the other side, which improves the prospects for a small decrease in the United States stocks, provided production declines and domestic deliveries are up to expectations.

NOTICE

STUDENTS EMPLOYMENT REGISTER,

The CANADIAN MINING JOURNAL has opened an employment register for students taking mining or metallurgical courses at Canadian Universities or Technical Colleges. Mine operators who wish to employ students during the summer months are requested to communicate with the Business Manager.

Students are requested to send in their names, along with brief records of experience. These will be filed and no effort will be spared on our part to place applicants in immediate communication with possible employers.

The Nissen Stamp

In Cobalt

NORTHERN CUSTOMS CONCENTRATORS, LIMITED.
COBALT, ONT., December 31st, 1909.

The Canadian Fairbanks Co., Toronto, Ont.

Dear Sirs :—

In answer to your enquiry regarding the Nissen Stamps supplied by your firm. These stamps are running steadily on some of the hardest rock on the Continent, they are crushing 5.3 tons of ore per head in twenty-four hours. The feed rolled down to go through about a one-inch hole.

The screen used for the above tonnage was 30 x 30 mesh, 28 gauge wire, opening .018. With a coarser screen the tonnage would of course be larger.

The shoes and dies wear even, and the splash is well distributed over the screen.

The arrangements for keeping up the weight of the stamps are very good. I can recommend the Stamps.

Yours truly, (Sgd.) F. J. Bourne, Superintendent.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

GEOLOGICAL SURVEY

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, and with many local areas and special subjects.

MARITIME PROVINCES

The whole of Cape Breton, and a large portion of the coal and gold fields of Nova Scotia, have been reported upon, and mapped on a scale of 1 mile to 1 inch. The remaining portions of the Province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter Provinces, mapped on a scale of 4 miles to 1 inch.

QUEBEC

Quebec, south of the St. Lawrence, has been reported upon, and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the Province north of the St. Lawrence are also available.

ONTARIO

A large part of the Province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

THE PRAIRIE PROVINCES

Geological maps and reports have been issued covering the greater part of the Provinces of Manitoba, Saskatchewan, and Alberta.

BRITISH COLUMBIA

The southern portions of British Columbia, as well as other parts of the Province, have been reported upon and mapped.

YUKON

Many of the important areas in the Yukon have been reported upon and mapped.

THE NORTH WEST TERRITORIES

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of a report or map will be sent to Canadian applicants free of cost, and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

Applications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.

THE FOLLOWING GEOLOGICAL MAPS HAVE RECENTLY BEEN ISSUED:

CANADA

1084. General Geological Map of Canada. Scale 100 miles to 1 inch.

NOVA SCOTIA

1019. City of Halifax Sheet.

1025. Waverley Sheet.

1037. Windsor Sheet.

The above sheets belong to the regular series of Nova Scotia map sheets on a scale of 1 mile to 1 inch. The first includes Halifax City and Harbour, the second the Waverley Gold District, and the third Gypsum Quarries.

ONTARIO

1023. Geological Map showing position of Corundum-bearing rocks in Central Ontario.

1076. Gowganda Mining Division.

This map besides representing the geology of the Gowganda area, represents the geography of a considerable area to the east and north.

980. Portion of Algoma and Thunder Bay districts, Ontario, 1908. W. J. Wilson.

1081. Region lying north of Lake Superior between the Pic and Nepigon Rivers, Ontario, 1906. W. H. Collins.

BRITISH COLUMBIA

1002. Geological Sheet, Special Map of Rossland.

This map, on a scale of 400 feet to 1 inch, besides accurately indicating the topographical and cultural features, shows the geology and location of veins.

1004. Geological Sheet, Rossland Mining Camp. Scale 1200 feet to 1 inch.

1074. Sketch map of Sheep Creek Mining Camp, West Kootenay, B.C., scale 1 mile to 1 inch.

YUKON

1041. Geological and Topographical Map of Whitehorse Copper Belt. Scale 1 mile to 1 inch. Also several detail maps of same belt.

NOTE.—Maps recently published may be had on linen cloth, for use in the field, at 10c. per copy.

REPORTS

1072. Summary Report of the operations of the Geological Survey for year 1908.

1085. Descriptive Sketch of the Geology, and Economic Minerals of Canada. G. A. Young. Introduction, R. W. Brock.

1075. Gowganda Mining Division, 1908. W. H. Collins.

1035. Coal Fields of Manitoba, Saskatchewan, Alberta, and Eastern British Columbia, 1908. D. B. Dowling.

1050. Whitehorse Copper Belt, Yukon. R. G. McConnell.

NEW CATALOGUE

1073. Catalogue of Publication 1843—1909.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

For nearly half a century the

Mining and Scientific Press

published in the great western mining centre has recorded the developement of the metal mining regions. Beginning with the industry itself, it has told from week to week the fascinating story of the progress of mining practice. It is edited and controlled by mining engineers for mining engineers.

Published weekly at 667 Howard St., San Francisco, Cal.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are: Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows:

All mines belong to the Goverment of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unserveyed territory, is open to prospecting.

Miners' Certificates good for a calendar year may be obtained by sending $10.00 to the Department of Mines. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minium being 40 acres in unserveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of $10.00 plus a yearly rental of $1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed territory may be purchased as a mining concession at the price of $20.00 per acre if within 20 miles of a railway in a straight line, or $10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

The Hon. Minister of Colonization, Mines and Fisheries
Quebec.

An Important Trio

Economics

Principles

Methods

Within a few months three highly important mining books have appeared, covering the practical, the fundamental and the economic phases. They are valuable books by thoroughly sound men of established reputations.

The Cost of Mining

By JAMES R. FINLAY

415 pages, 6x9, illustrated

$5.00 (21s.), net, postpaid

An economic investigation of the cost of scientific, profitable mining. It contains valuable data obtained from official reports of the mines producing 75 per cent. of the metal under discussion. Detailed analyses cover costs of mining **coal, iron, lead, zinc, copper, gold** and **silver.**

Contents: Value of Mining Property, Factors Governing Variations, Partial and Complete Costs. Statistics of Coal Production. Costs of Mining Coal. Cost of Mining Lake Superior Iron. Occurrence and Production of Copper. Lake Superior Amygdaloid Copper Mines. Conglomerate Copper Mines of Lake Superior. Copper Mines on Fissure Veins in Montana, Australia and Arizona. Various Copper Mines of Arizona and Mexico. Copper Mines in various other Districts. The Copper Mining Business in General. Lead. Silver-Lead Mining. The Cost of Silver-Lead Smelting. Zinc Mining. Occurrence and Production of Gold. Quartz-Pyrite Gold Mines. Cripple Creek. Kalgoorlie and Goldfield. Silver Mining at Cobalt and Guanajuato.

Principles of Mining

By H. C. HOOVER

200 pages, 6x9, illustrated

$2.50 (10/6), net, postpaid

The principles of mining as developed by modern science and business methods are here fully discussed under the general headings of Valuation, Organization and Administration. Important chapters cover investment from the public's standpoint, and the character, training and obligations of the mining engineer.

Part I deals fully with the determination of value, prospective and in sight—the sizing up of the mine—and in this Mr. Hoover's work has been extensive and highly successful.

Part II discusses the development of tunnels, shafts, crosscuts, etc., with chapters on mechanical equipment and efficiency.

Part III. Administration of mines with all the problems of labor efficiency, labor unions, wages, working costs, accounts, division of expenditure, etc.

The main chapter headings are: Valuation of Copper, Gold, Lead, Silver, Tin and Zinc Lode Mines. Mine Valuation. Development of Mines. Stoping. Methods of Supporting Excavation. Mechanical Equipment. Ratio of Output to the Mine. Administration. The Amount of Risk in Mining Investments.

Timbering and Mining

By W. H. STORMS

300 pages, 6x9, fully illustrated

$2.00 (8/6), net, postpaid

Deals with practical methods, not theories. A straightforward account of the best, safest and most economical methods employed in the leading American mines.

Contents: Introduction. Timber Used in Mining. Preservation of Timbers. Drifting and Drift Sets. Driving Lagging in Drifting. Driving in Running Ground. Breast Boards. Structural Steel in Mine Workings. Timbering Drift Gravel Mines in California. Shafts. Location, Kind and Size of Shafts. Prospecting Shafts in Good Ground, and Those Requiring Close Timbering. Cribs and Single Compartment Shafts. Size and Division of Working Shafts. Drainage. Position of Temporary Hoisting Plant and Permanent Plant. Size of Shaft Compartments. The Collar. Hanging Belts. Cross Head in Sinking Shafts with a Bucket. Stull Methods in Many Small Mines of the Cobalt District, Ontario. Bucket Dumping at Vertical Shafts. Bucket Dumping at Inclined Shafts. Framing Shaft Timbers. Butt Corner and Dove-Tail Corner Methods. Framing for Vertical Shafts. Divider and Spliced Wall Plate. The Template. Placing Timbers of Shaft Sets in Position. Placing Timbers in Inclined Shafts. Lining the Sets. Difficulties in Sinking Through Running Ground. Sinking Through Running or Loose Ground. Combination Vertical and Inclined Shafts. Bearers in Shafts. Fenders for Protection of Shaft Timbers When Blasting. The Cable Mat. Extension Tracks for Sinking. Inverted Rails. Sinking Ladders.

We can supply any engineering book in print.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

Head Office: 4 Hospital Street, Montreal

MANUFACTURERS OF

High Explosives, Stumping Powder, Blasting and Sporting Powder, etc.

Safety Fuse, Electrical Fuses, Batteries, and other Accessories.

Three Post Magneto Electric Blasting Machine

NOBEL GELIGNITE

It always breaks cleanly to the bottom of the drill holes and is free from fumes of any kind Equal to 75% Dynamite and is sold at a price producing very much better results in terms of Rock Broken or Extracted and money spent.

"WINTER BRAND" DYNAMITE

Is only one strength, if anything, a little stronger than 50% Dynamite. **It does not freeze,** or rather, explodes with perfect efficiency when frozen **and needs no thawing.**

"AUTUMN BRAND" DYNAMITE

Is packed in all the usual percentages. The powder is similar in appearance, character and effect to ordinary Dynamite, except that the freezing temperature of the Nitro-Glycerine is reduced from 42° F to a little under 30° F.

PERMITTED EXPLOSIVES for Coal Mines

Nobel Monobel, Saxonite and Carbonite.

"CLEVELAND" STOPE DRILLS

EFFICIENCY:—Of course you want the stope drill which has the highest efficiency, but you must pick out the one that will have as high an efficiency a year from to-day. Isn't it true that your stope drills decrease steadily in efficiency as they grow older?

REPAIRS:—Repairs which must be made from time to time after the part has given long and satisfactory service, are not a source of dissatisfaction, but dont you find that your stope drills are constantly needing something new?

DRILLING CAPACITY:—As long as your stope drill will put in sufficient holes per shift to drill up your stope there is no argument in favor of your changing to our drill just because it will drill faster. We know that. But we know that the "CLEVELAND" Stope Drill will do as much work per shift when it is one year old as it will when one week old, and that is what you want, isn't it?

THE "CLEVELAND" Whether you purchase your stope drills after considering efficiency, repair cost, or drilling capacity, the "Cleveland" should be the stope drill you specify, for its design is such that the initial efficiency is the highest possible in an air tool, and the piston and valve action are so related that the "Cleveland" is just as efficient when it is a year old as when it is brand new; we **know**, and our information is gained from hundreds of installations that the "CLEVELAND" will cost less for repairs **per year** than any stope drill made; a 30 day trial will convince you that the "CLEVELAND" will drill as much per shift as any other stope drill, and we have machines always in stock ready to ship for trial if you will drop us a line, As you have everything to gain and nothing to lose, why not investigate NOW?

Sullivan "CE" Mining Machine crossing the face of a room.

COAL MINE
DEVELOPMENT

may be carried on most rapidly and a paying tonnage established at the earliest possible date, with Sullivan Continuous Undercutters.

These machines are well suited to driving entries, cutting room necks, break-throughs and other narrow work, by reason of their compactness, the ease with which they are handled, under their own power, and their high mining speed on the "continuous cutting" principle.

Amatite ROOFING

NEEDS NO PAINTING

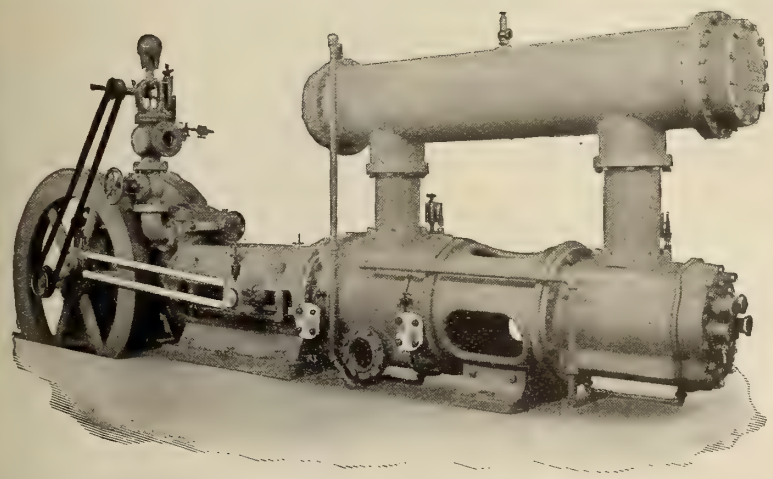
MOST ready roofings require special painting and coating, and unless this is done regularly, you are sure to have leaks and trouble right along.

If you use Amatite, nothing of the sort is required. You will have real roof protection *without painting* of any kind.

Amatite is made to stay waterproof and give protection year after year, without any thought or care on your part.

First—Because it is waterproofed wtth Coal Tar Pitch.

Second—Because it has a real Mineral Surface.



Amatite, owing to these features, is the most economical roofing made. Its first cost is low, and you are *saved* all future expense for repairs or paint because it will need neither.

If you haven't seen Amatite, write for a sample to-day. From it you will very quickly understand why it doesn't require painting; why it does not leak; and why it saves you money.

Address nearest office to-day.

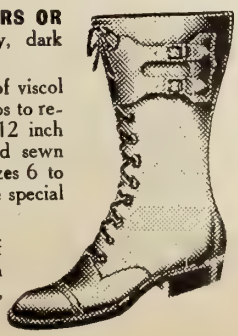
THE CALL OF THE WILD.

The Opening Season is calling hundreds of enthusiastic prospectors away to their summer's labor in the wilds.



If you are Going, What About Requirements?

In many lines we are peculiarly fitted to help you get your outfit. From watches, instruments and firearms to tents, flybars and clothing we handle most of the necessaries.

OUR SPECIAL BOOT FOR MINERS OR PROSPECTORS is made from heavy, dark "tan colored" winter calf.

The leather is treated in a solution of viscol oil, makes them soft and pliable, helps to resist the wet. It's high cut having a 12 inch left with heavy double goodyear welted sewn soles and bellows tongue to top. Sizes 6 to 11. The highest kind of value at the special price per pair $6.00.

NOTE:—We recommend the use of "Visole" to be applied freely which will give additional wear to the leather, per tin .15c.

Compound arnica and witch hazel. This is the best preparation we know of for putting on bruises, if applied immediately it saves the hurt one much suffering, it soothes the pain and reduces the swelling, the bruise not getting black at all. Price pint bottle .50, quart bottle 1.00, small bottles .15 and .25.

Mosquito and black fly oil applied over the exposed parts, will prevent insects from biting, 4 oz bottle .25, per gallon 7.25

Peruvian Ointment, an antiseptic healing ointment for burns, scalds, cuts, sores, etc. Price per bottle .15, per lb. jar .75

Bandages (cotton) all 6 yard lengths,
1 inch wide.....2 for 5 per dozen .30
2 " " .....5 each, 6 for .25
2½ " " .....5 each, per dozen .60
3 " " .....2 for .15, 4 for .25

Zinc Oxide Adhesive Plaster on spools, 5 yard lengths, For strapping up cuts, broken ribs, or any purpose where strapping is necessary. ½ inch wide .30 each: 1 inch wide .40 each: 2 inches wide .60 each.

New skin, an antiseptic waterproof liquid court plaster, for cuts, burns, blisters, etc. Price .15.

Fine cold drawn castor oil, pint bottle .20

Lewis Astringent cordial for diarrhoea, cramps, etc. 4 ounce bottle .25

FIRE LOSS AND MINERAL PRODUCTS.

We have read no more eloquent plea for the use of mineral products—and we use this term in its widest sense—in the construction of buildings than that contained in a bulletin just issued by the United States Geological Survey.

Investigations made by officials of the Survey have adduced many startling facts. For instance, the fire loss in the United States during 1907, excluding forest fires and marine losses, was more than $456,485,000. The actual fire losses due to buildings and their contents destroyed meant a per capita loss of $2.51. In Europe, due largely to the absence of frame buildings, the per capita loss is as low as 33 cents.

It is probable that the per capita loss in Canada is as large as, if not larger than, that of the United States. In both countries frame buildings are common. In both, also, there has been until recently, no organized effort to impress the public with a sense of the irremediable and appalling losses incurred through fire.

While in our larger cities fireproof business structures are the order of the day, it is yet true that the vast majority of Canadian dwellings, shops, warehouses, factories, and public edifices are either completely inflammable, or only partly fireproof. Our principal efforts to guard against fire and its results are respectively our fire-fighting brigades and our insurance systems. These, in themselves, constitute heavy annual drains on our resources. Insurance, in any form, is merely a means of indemnifying the individual at the expense of the community. Like fire-fighting organizations, insurance is a costly superfluity. The one and only adequate preventive of waste through fire is a change from our present methods and materials of construction.

In effecting this change,—a change implying the more general utilization of mineral products such as brick, concrete, building stones, slate, tiles, metallic members, and insulating material such as asbestos, mica, and slag products,—the mineral industry will be given a tremendous impetus. And, instead of depleting our forests to erect perishable and unsightly structures, we shall put a premium upon architectural permanence and fitness.

As we have pointed out above, the materials that go into our modern office buildings are fireproof. But the myriad small buildings and dwellings that dot the country and make up our villages and towns are composed in nine cases out of ten of wood. In some parts of the Dominion this is not avoidable. But in Nova Scotia, in parts, at least, of New Brunswick, and Quebec, and throughout large portions of Ontario and Manitoba, fire-resisting material is as cheap, or almost

as cheap, as wood. Further, it is only a question of time when similar conditions will obtain in Alberta and the West generally.

While we must acknowledge that wood as a building material cannot be replaced in every part of Canada, yet measures can be taken to render wooden houses comparatively unburnable. Asbestos sheathing affords probably the best protection. Asbestos shingles, tiles, boards, in all manner of shapes are being put on the market. Metallic sheathing is also a useful, though not ornamental, means of protection. It is worthy of mention that for years the fire laws of Dawson City, Yukon Territory, have made obligatory the sheathing of buildings with uninflammable substances.

But it is in our larger centres of population that a change is most needed. Wooden floors, partitions, staircases, should long ago have disappeared from our public buildings. The use of reinforced concrete, or of some equivalent, should be enforced by law in all cities. In suburban and country communities, measures only less stringent should be put into effect.

All this, naturally, cannot be done at once. It will take years to form public sentiment. But we are convinced that this is a subject that should be discussed by our legislatures and, in fact, by all our city, town, and county councils. The loss that Canada suffers annually through fire, is enormous enough; but another and a heavier toll is paid. Dozens, perhaps hundreds, of human lives are sacrificed because as a people we are ignorant and indifferent.

In developing our theme we fear that we have overlooked our original text. What we started out to say was that before the captains of our asbestos, cement, clay, mica, and iron industries lies the opportunity of educating the people up to the use of safe materials of construction. Sooner of later this must come. Canada should not be the last of civilized countries to remove the scales from her eyes.

PRODUCER-GAS POWER PLANTS.

Despite many failures, failures due both to inefficiency on the part of operators and to inherent defects in the plant itself, the gas-producer as a source of power is more than holding its own. Trouble has arisen in not a few Canadian installations. In several instances that have come to our notice the manufacturers have been to blame. In other instances the ignorance of the operator has brought disaster. But, on the whole, the gas-producer has established itself as one of the few economical sources of power.

Such is the present demand for producers and gas-engines that one new Canadian manufacturing concern, organized but a few months ago, has orders on hand that will tax its capacity for two years to come. Both British and United States manufacturers report excellent business.

But while no one can dispute the fact that the producer and gas-engine are to play a large part in our industrial growth, it may not be amiss to allude here to the tendency towards disregarding local conditions in considering the selection of a power plant. Our remarks apply, of course, only to the equipment of mines.

The belief that the gas power plant is bound to replace all steam installations is not warranted. Initial cost of plant, transportation charges, the probable life of the mine, and the probable net earnings throughout its lifetime, must all be weighed carefully. Due consideration of these factors will frequently lead the engineer to conclude that he must sacrifice actual mechanical efficiency and must be influenced mostly by the immediate requirements of his mine. In other words, a cheap steam plant, representing only a small outlay, often serves the purpose with more ultimate economy than would a more elaborate and costly outfit. It may be bad engineering to install a producer-gas power plant if a non-condensing Corliss engine will fill the bill.

That our meaning may be clearer we may add that we have no shadow of doubt as to the assured future of the producer-gas plant. It has come to stay. Its use will extend. But, for the present at least, there are limits set. These limits must be recognized. The engineer must not allow himself to be carried away by the mechanical beauty of a device that is sometimes unsuited to meet the requirements of mines situated far from transportation; or that, in point of cost, throws out of balance the mining business that he is conducting.

As our transportation lines improve and increase, and as suitable fuel becomes cheaper, the steam plant will gradually be replaced. But its days are not yet numbered.

TWO RECENT CANADIAN INVENTIONS.

Two Canadians have recently entered into the field of invention in mining machinery. Mr. John Redington, mine manager of the Coniagas Mine, Cobalt, Ont., has introduced several modifications in the standard design of rock-drill valve and piston. Ten of his drills are in use at the Coniagas mine. The parts are machined and assembled at the mine. The drill is reported to be giving every satisfaction.

Another invention, a rock-drill chuck, patented by Mr. H. W. Schorlemmer, Rossland, B.C., has been given full trial at the mines of the Consolidated Mining & Smelting Company. In the new chuck there are no bolts and nuts to tighten; the operator merely slips in his drill and turns on the air. The drill tightens automatically, and does not work loose. To release the drill it is only necessary to tap a wedge which is part of the chuck.

NEW DEMANDS OF THE U. M. W. A.

Following a visit from Mr. E. S. McCullough, ex-vice-president of the U. M. W. A., to Port Morien, the North Atlantic Collieries Company, has been served with notice by a local of the U. M. W. A. of various demands. These are as follows: Recognition of the United Mine Workers, reception of their pit committee, granting of a "check-off" system, permission to inspect the balance sheet and books of the company at intervals to see whether or not an increase of wages is justified, and an undertaking on the part of the North Atlantic Company not to mine or load any coal for any company at whose mines members of the U. M. W. A. may be employed. These are modest demands. This occurrence but serves to emphasize our previous contention, namely, that Canadian companies are at the mercy of the heads of the international labour unions.

Take this particular instance as a case in point. The North Atlantic Collieries is a small concern, which has never at any time been very remunerative. No matter how preposterous the demands of an international union, nor how small the Canadian company, there is nothing in our laws to prevent the whole financial force and the whole official personnel of the union from being concentrated upon one single devoted company. Instructions can be issued in the United States and carried out in Canada. American money can be used without let or hindrance to destroy Canadian industries, and apparently no power in our country can say nay. What magic is there about a labour union that it should be exempted from the ordinary protective laws which a sovereign country exercises over the actions of aliens within its borders? The United Mine Workers of Canada is not an incorporated body, either in the United States or in Canada; its officers report to no government authority; its finances are untrammelled by legislation that joint stock companies must recognize. Canada is usually supposed to be a free and democratic country, affording to its citizens the rights of individual liberty. But the fact remains that its citizens can be prevented from exercising their right to work, and the investments of other citizens can be rendered worthless at the beck of a labour leader in the United States. Ottawa cannot prevent the alien from sending his money here, nor can Ottawa deport the undesirable agitator when he is stirring up strife. The situation would be amusing were it not so humiliating. We erect a high tariff barrier against United States imports that interfere with our industries; we bar the willing European worker, no matter what his qualifications, unless he can produce twenty-five dollars; we deport the indigent and the feeble; we keep out the immoral and the diseased; but the international union delegate who comes in the sacred name of labour is admitted and allowed to remain, no matter how incendiary his speeches nor how dangerous his mission to our industries and our workers.

GRANBY AND SOME DEFINITIONS.

After reading current reports of the Granby mix-up, we are struck with the fact that much of the difficulty might have been obviated had the phrases "ore in sight" and "ore reserves" been used in their right technical sense. The loose allusions made by Manager Hodges to "ore in reserve" must have referred to probable or indicated ore. By no stretch of the imagination can we conceive of an experienced mining man speaking thus of ore positively blocked out and ready for stoping.

Thus when we are informed that Dr. Sussman reports 6,000,000 tons as ready for stoping, we cannot see that the position of Granby is bad. This quantity will provide about five years' ore supply at the present rate of consumption. This is all that can be expected, so far as "ore in sight" is concerned.

The future of Granby hinges, therefore, upon those ore supplies, not yet blocked out, ready for stoping, or "in sight," but falling into the category of "probable," or "indicated." Just how far these bodies have been explored remains to be seen. But certainly their extent, or, rather, the presently available knowledge of their extent, is the crux of the Granby question.

BUSINESS HONOUR.

An exceptional instance of honourable business methods has come to our notice. Our readers are familiar with Stevens' Copper Handbook. This annual contains a number of pages of advertisements. Usually the volume is revised completely every year. For two years past Mr. Stevens has been unable to revise the volume completely. Feeling that this fact will affect the circulation of the book, Mr. Stevens has, nevertheless, notified each subscriber. Further, considering it prejudicial to lower his advertising rates, but feeling, also, that he is not justified in charging full rates, Mr. Stevens has decided to reprint all advertisements for this year free of charge.

The frankness and candour with which Mr. Stevens has faced the situation are refreshing, and, so far as our experience goes, unique.

GRANBY AFFAIRS.

Elsewhere we publish a communication dealing with the Granby muddle. Our correspondent points out that if it be true that ore available is limited to six million tons, then an independent examination should be demanded at once. Statements made within the last two years by Mr. A. B. W. Hodges, who recently resigned the managership, indicated his belief that much larger quantities were in sight. The late slump is attributed to rumours contradicting Mr. Hodges' assertions.

It is neither wise nor desirable to diagnose the trouble at its present stage. But it is imperative that full investigation be made without delay. The directors must spare no pains to clear themselves. The pub-

lic has a right to know whether stupidity or something less excusable has brought about the present unfortunate circumstances.

THE LAST STRAW.

We must express our sympathy for the unfortunate crusaders who, a few weeks ago, dashed to the Camel's Back region—and returned. For those who negotiated the slushy spring trails there was little humour in the episode. They will scarcely rise to the bait so easily again. The men who started the false rumour of discoveries need a severe lesson..

The fact remains that northern prospectors are too readily stampeded. Reports of new finds are always, or nearly always, discountable. The best policy is to study the country carefully, to make one's plans with equal care, and then follow out those plans to the letter. Prospecting should be systematic. Wild excursions into the bush do not pay.

EDITORIAL NOTES.

Apart from obvious physical advantages nickel coins would advertise Canada's resources. The matter should be pressed upon the proper authorities.

The new price set by the Dominion Coal Company on coal sold to the Dominion Steel Company is $1.55 per ton. The former price was $1.28 per ton.

The output of the Western Fuel Company, Nanaimo, B.C., was 48,000 tons during March. This is 3,000 tons larger than any monthly output in the history of coal mining in Nanaimo.

Canadian architects are not as familiar with the uses of asbestos as might be expected. Few of them have had occasion to use it extensively. This should not be the case. Practical immunity from fire risks can be had very cheaply by using manufactured asbestos.

ANNUAL REPORT OF THE NOVA SCOTIA DEPARTMENT OF MINES FOR 1909.

The annual report of the Nova Scotia Department of Mines shows, once again, a decided improvement in form and arrangement. While there is still much room for change, especially in the matter of statistics, we are glad to note that the Department is making some progress. We suggest, as we have suggested before, that the mine accidents be summarized and resolved into rate per thousand men employed. Moreover, some effort should be made to embody in a tabular statement the tonnage and money value of all mineral outputs for the year.

COAL TRADE.

The returns of coal sold during the year 1909 show, compared with the returns for 1908, as follows:

	1908.	1909.
Nova Scotia	1,950,632	1,769,803
New Brunswick	510,331	542,827
Newfoundland	207,062	156,248
Prince Edward Island	63,331	78,898
Quebec	2,047,638	1,508,817
United States	499,634	320,735
Mexico	8,907	.....
St. Pierre	.....	10,235
Other countries	4,697	755
Bunker	193,352	227,395
	5,485,583	4,615,713

Coal Production by Counties.

	1908.	1909.
Cumberland County, tons	559,013	542,040
Colchester County, tons	3,951	1,330
Pictou County, tons	777,217	667,637
Cape Breton County, tons	4,556,446	3,634,392
Inverness County, tons	402,655	362,516
	6,299,282	5,207,915

COAL MINING.

Notes from Inspectoral Districts.

Southern District of Cape Breton.

Dominion No. 2 Colliery.—There are 235,000 feet of air in circulation in this mine. One Dixon fan, 29 by 9 feet, produces the current. The seam is 7 feet 6 inches thick, with a pitch of 5 1-2 per cent.

The method of timbering is props-and-caps. Minimum diameter of props is 4 inches.

The colliery has a complete water system. Every thousand feet there are connections with air lines. Working places are sprayed every night. Ackroyd and Best safety lamps are in use. The pit bottom is arranged with revolving tipples and storage tanks. Compressed air is used as motive power.

Excellite powder is used.

Haulage is all plane-rope, except on levels to pit bottom, where air locomotives are used. Room-and-pillar system is followed.

Dominion No. 3 Colliery.—There are 50,000 cubic feet of air in circulation in this mine. One Capell fan, 13 1-2 by 7 1-2 feet, is in service.

Coal seam is 7 feet 6 inches thick, pitching 8 per cent. The mine is worked on the room-and-pillar system.

The compressed air pipe can be coverted into a water line. Ackroyd & Best safety lamps are used.

Dominion No. 4 Caledonia Colliery.—The ventilating of this mine is done by one Dixon fan 14 by 6.4 feet, and one Murphy fan, 12 by 6 feet, delivering 100,000 cubic feet of air. Seam is 7 feet thick, pitching 8 degrees. Props used measure 5 inches at the small end.

The mine is worked on the room-and-pillar method. Rooms are 20 feet wide. Pillars under land area are from 25 to 35 feet thick; under the sea area from 27 to 40 feet thick.

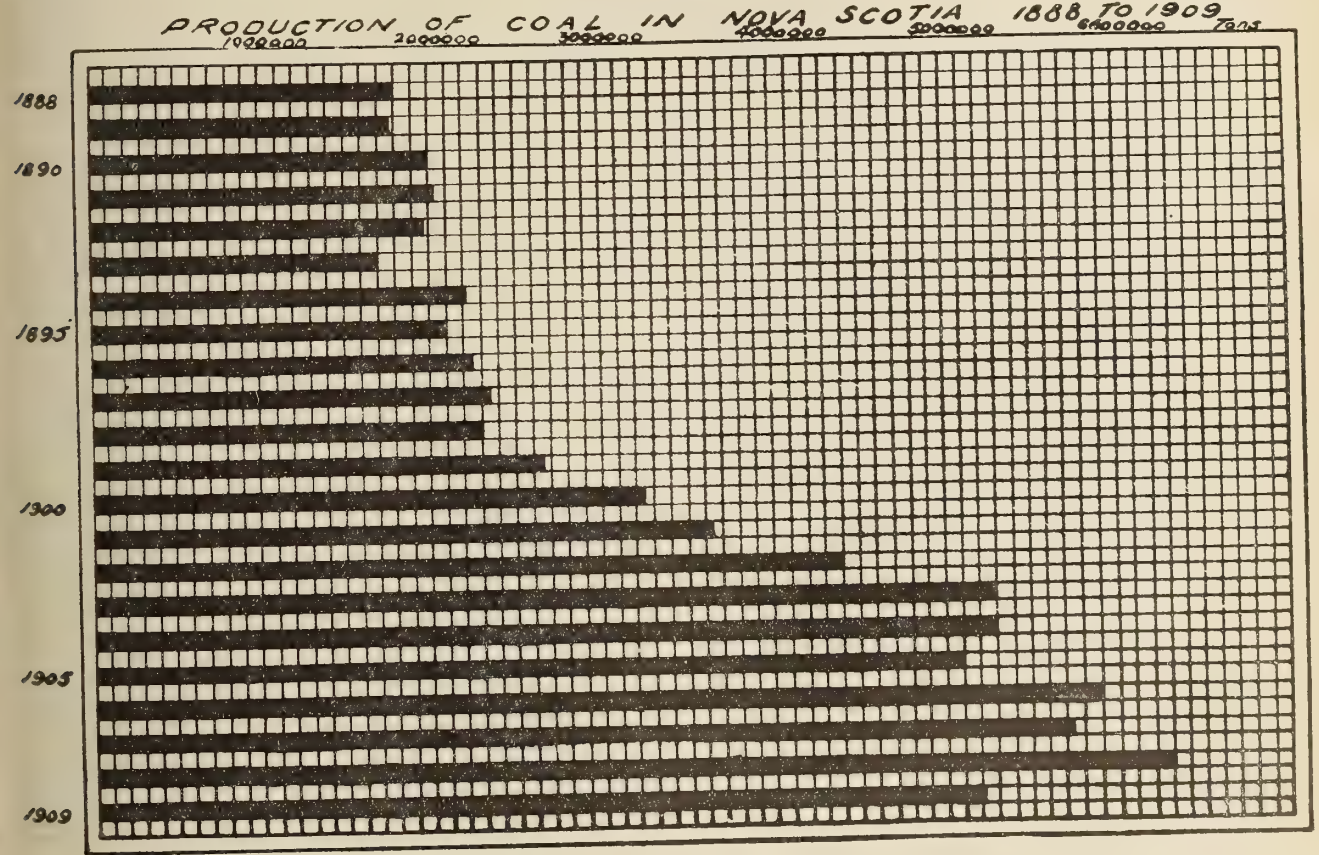
The water for steam and for fire protection is drawn from the town system. Ackroyd & Best safety lamps

re used. The explosives used are Excellite, in pillars; nd Bulldog, in rooms and narrow places.

Endless haulage on the deeps and main level.

DOMINION No. 5 COLLIERY.—Air, 190,000 cubic feet, s supplied by two fans—one 24 foot Guibal, and one 5 foot Chaneller. Room-and-pillar. Ackroyd & Best amps.

DOMINION No. 6 COLLIERY.—One Walker fan, 20 by 7 eet, supplies 48,172 cubic feet of air. Bord-and-pillar nethod in mining. Ackroyd & Best lamps. Bulldog owder. Five and one-half tons of coal are produced or each pound of powder used.



DOMINION No. 7 COLLIERY.—One Capell fan, 12 feet y 11 feet 6 inches, supplies 60,000 cubic feet of air. Room-and-pillar. Bulldog powder.

of similar capacity is held in reserve. Both endless and plane haulage systems are in vogue.

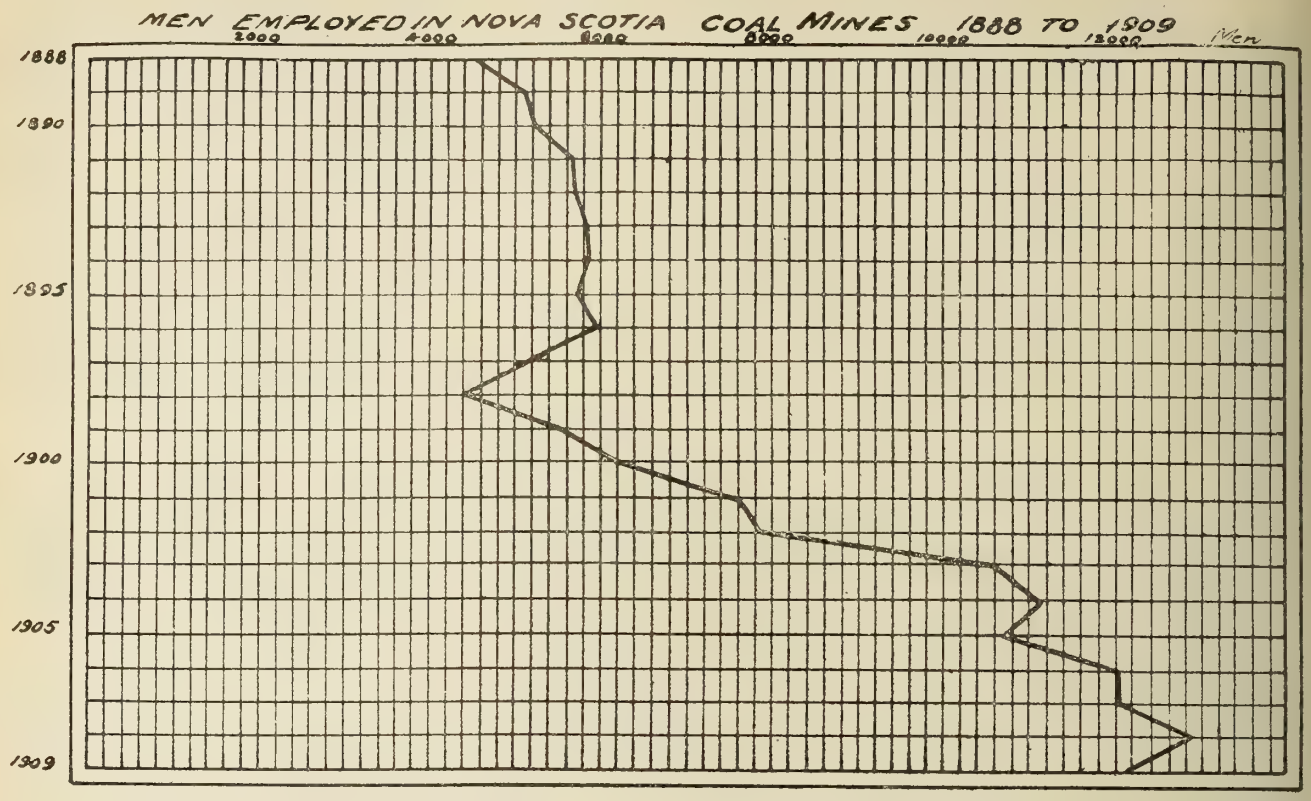
N. S. STEEL & COAL CO., SYDNEY No 2 COLLIERY.—Bord-and-pillar system. Coal all mined by machines of the Hardie and Whitcomb type, driven by compressed air. Marsant safety lamps.

SYDNEY COAL COMPANY.—Employs only 10 miners and 5 unskilled workmen. Open lights are in use.

N. S. STEEL & COAL CO., SYDNEY No. 3 COLLIERY.—On a seam 4 1-2 to 5 1-2 feet thick, three parallel slopes now down 8,885 feet are driven. Daily output, 1,000 tons. Method of working, bord-and-pillar. Width of rooms, 20 feet. Pillars, 25 feet to 40 feet, according to cover. Cross-cuts driven every 60 feet. Coal cutting machines, puncher type, are operated by compressed

DOMINION No. 8 COLLIERY.—One Murphy fan, 8 feet in diameter, supplies 58,000 cubic feet of air. Bord-and-pillar. Marsant safety lamps. Bulldog powder. Endless haulage.

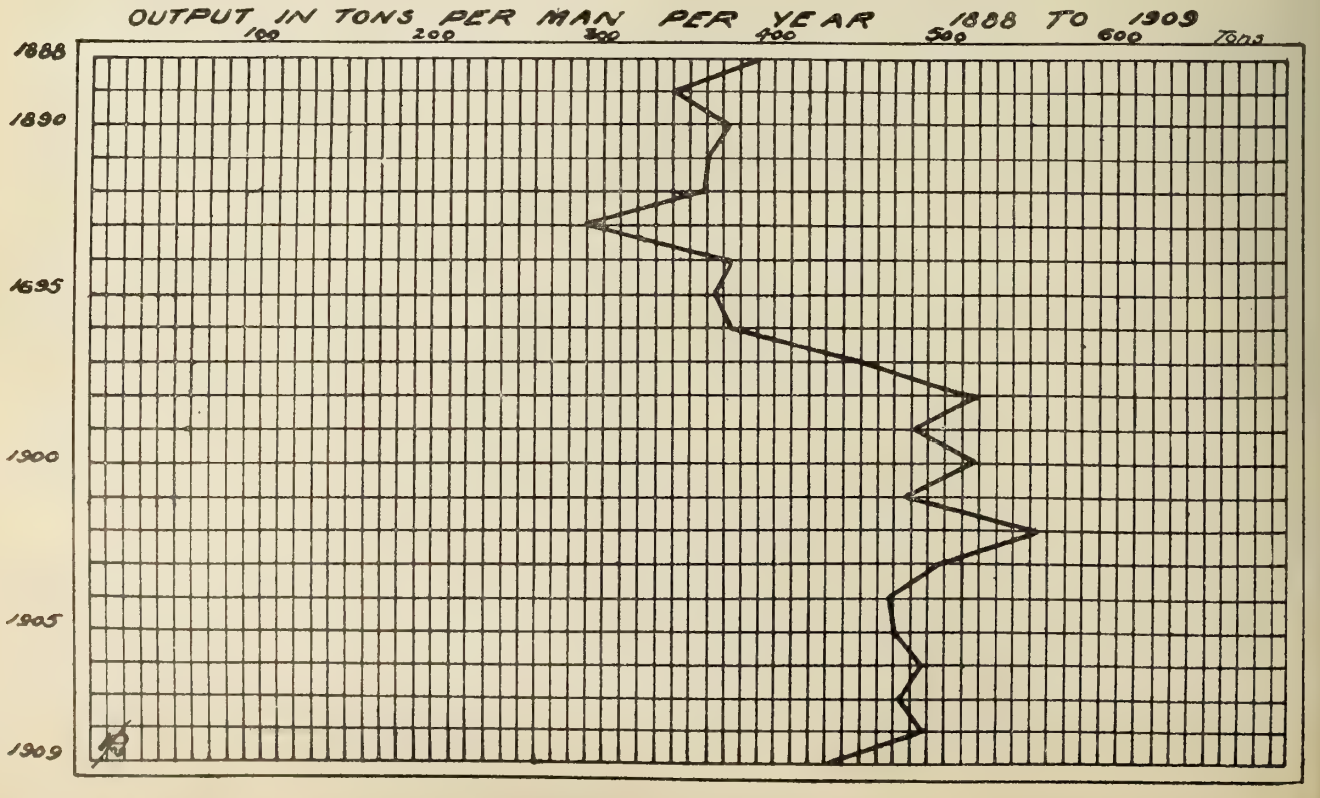
DOMINION No. 9, DOMINION No. 10, and NORTH ATLANTIC COLLIERIES complete the list in this district.



Northern District of Cape Breton.

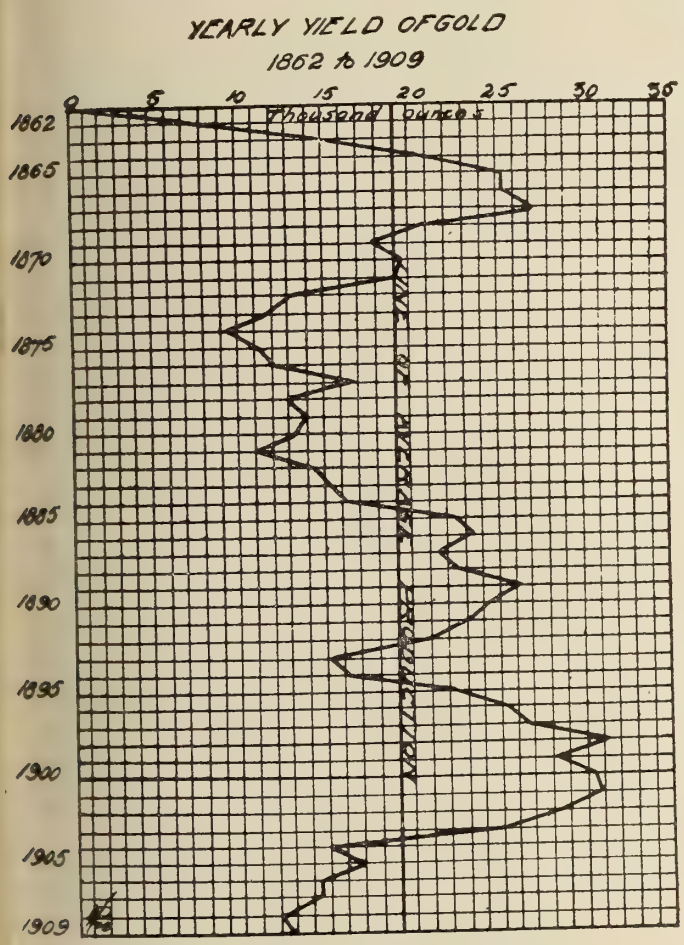
N. S. STEEL & COAL CO., SYDNEY No. 1, COLLIERY.—877 men are employed here. The output during the year was 250,470 tons, of which amount 118,284 tons were mined in pillars. Bulldog powder was used to the extent of 21,361 lbs. Thickness of seam, 5 feet to 6 feet. Coal, soft and gaseous. Roof and floor are shale. System of working is room-and-pillar, rooms being 17 feet wide and pillars 60 feet thick, with crosscuts driven every 60 feet. Coal all mined by hand picks. A Capell fan, 20 feet by 5 1-2 feet, delivers 120,000 cubic feet of air. A spare 30 by 10 Walker-Guibal fan air. Asbestos fibre brattice cloth and board are used. Marsant lamps. Endless haulage. One Capell fan, 15 by 7 1-2 feet, delivers 48,985 feet of air. An auxiliary fan, a Murphy, 10 by 6, delivers 59,900 feet.

N. S. STEEL & COAL CO., SYDNEY No. 4 COLLIERY.—Coal mined by means of four class E.6 Sullivan electric coal cutters; also by hand. Plane haulage. Bord-and-pillar. One Sirocco fan, 4 1-2 feet diameter, 5 foot blade; and one Sturtevant fan, 6 feet diameter, 3 foot blade. Marsant lamps. Monobel explosives.



N. S. STEEL & COAL CO., SYDNEY No. 5 COLLIERY.—Bord-and-pillar. Asbestos fibre brattice cloth. Bulldog compressed powder. Endless haulage. Marsant safety lamps.

Dominion No. 1, No. 12, No. 14 and No. 15 Collieries, and the workings of the Colonial Coal Company and of the Mackay Mining Company, make up the remaining mines of this district.



Pictou County.

Acadia Coal Company, Albion Mines, Stellarton.—Here three seams are worked, Cage-Pit, McGregor, and Third. The Cage-Pit seam, 14 feet thick, has an average pitch of 25 degrees. Pillar work was the principal work done. The Third seam, 12 feet thick, is also producing. 270 Wolff safety lamps are used; there being 385 in stock. Monobel explosive, to the amount of 16,682 pounds, and 32,898 detonators were consumed during the year. The air pipes on the main haulage ways are fitted with connections and valves, so that they can be converted into a water system in less than five minutes. The Allan Shafts, owned and operated by the Acadia Coal Company, were not so actively developed as during 1908. Water in the Ford pit hampers work in these shafts. Work has been principally confined to the Ford seam in No. 2 shaft. No. 1 shaft output only 6,559 tons. Monobel explosive was used. Wolff safety lamps.

ACADIA COLLIERY.—Work here was also curtailed to a ertain extent. The airways are reported to be in a ery bad condition, and insufficient air is supplied. The ine is worked longwall, the length of each wall being 7 feet from lowside to lowside. Tarred canvas and, in ome cases, boards are used for brattice. No explosives re needed. Wolff safety lamp. A 13.6 by 4 Capell an, driven by a 100 h.p. Robb Armstrong tandem en- ine, supplies air. Vale Colliery, Thorburn, has been ell developed. Bord-and-pillar system and longwall. Ackroyd-Best and Marsant lamps, with electric lighters nd patent re-openers at the surface and mine stations. Monobel explosives. One 28-foot Walker fan.

INTERCOLONIAL COAL COMPANY.—The Drummond Col- iery was in steady operation. The mine is divided into ections. In No. 1 section no explosive is used. Excellite owder is used in No. 2 and No. 3 sections. Tarred can- as is used for brattice. Marsant lamps with plug lock. One 20 foot 6 inch indestructible Walker fan supplies ir. All the underground engines are run by compress- d air.

Cumberland and Colchester Counties.

CUMBERLAND COAL & RAILWAY COMPANY, SPRINGHILL COLLIERIES.—Good deal of development work done. Dynamite and saxonite are explosives used. Capell fans. Marsant lamps. Lino-tarred brattice cloth.

MINUDIE COAL COMPANY, MINUDIE MINE—River Hebert. Slope is down 2,300. Development work is being pushed. A Stine fan supplies 25,000 cubic feet of air per minute. Asbestos brattice cloth. No spraying apparatus. Black powder and dynamite. Open lights. Longwall advancing. The three-foot seam has a clay parting in centre. Seam pitches at angle of 19 degrees.

MARITIME COAL, RAILWAY & POWER COMPANY, JOGGINS MINE.—Steady progress here. Haulage system changed from tail-rope to endless. New tipple, screen, and picking tables, and 36 new tenement houses. One Sturtevant fan, 7 feet by 8 feet 9 inches, supplies 20,000 cubic feet of air. Seam four feet, pitching 17 1-2 degrees. Bord-and-pillar and longwall systems. No spraying. Marsant lamps. Tarred cloth for brattice. Black powder and dynamite. Chignecto Mine, operated by the same company, worked steadily. Bord-and-pillar and longwall. Open lights. Black powder. Main-rope haulage. One 14-foot fan made by Londonderry Iron and Mining Company, direct connected.

The Fundy Mine is closed. So also is the Great Northern, one of "Dr." Hugo Von Hagen's fakes. The Jubilee and De Bert mines are doing nothing. The Strathcona mine, River Hebert, produced 5,835 tons.

Inverness County.

INVERNESS MINE (McKenzie & Mann).—Fair development here. Bord-and-pillar and longwall. Both tail-rope and horse haulage used. One 7 by 18 Walker fan. Austen's No. 2 twill brattice cloth. Acadia No. 3 blasting powder. Although the mine is reported to be non-gaseous, Marsant safety lamps are used throughout.

THE MABON MINE, MABON, was operated by the Government for five months. It is now flooded.

THE PORT HOOD-RICHMOND COAL & RAILWAY COMPANY.—The Port Hood mine of the company. Slight decrease in output owing to strike. One 6 by 14 Dixon fan supplies 50,000 feet of air. Seam is 6 feet thick, pitching 22 degrees. Bord-and-pillar. Rooms, 14 feet wide; pillars, 35 feet. Mine is dust free. Gaseous. Ackroyd & Best magnetic lock safety lamps. Monobel powder.

Coal Mine Accidents.

These will be the subject of a separate article. It may be noted, however, that no proper statistics are set forth in the Annual Report. This is a lamentable omission.

GOLD.

During the year 19 companies, operating in 19 districts, produced 12,597 ounces from 59,058 tons of ore, a slight increase over the preceding year. The total value was $239,353; the average value per ton being $4.05. This latter figure is 24 cents greater than the average for last year. About 500 men were employed. No fatalities occurred.

We shall glance over a few of the larger concerns.

Guysboro County.

THE NEW ENGLAND MINING COMPANY (formerly the Boston-Richardson Mining Company), Isaacs Harbour. 88 men were employed here. 41,425 tons of ore yielded 5,024 ounces of gold, valued at $95,456. 82.6 per cent. of the total was recovered by stamp amalgamation; from 1171.5 tons of concentrate, 17.4 per cent. The increase indicated over the previous year is 3,425 tons crushed and 938 ounces gold recovered. The average yield per ton is 24 cents higher. The reported costs were $1.07 for mining; for milling, including bromo-cyanide treatment of concentrate, $0.71 per ton of ore. The actual cost of bromo-cyaniding one ton of concentrate was $3.06. The average recovery was 78.7 per cent. At the end of September the broken ore in mine was estimated to be 18,000 tons.

At a small working at Lower Seal Harbour, Edgar

Silver and others mined and milled 393 tons of ore, yielding 288 ounces of gold.

THE SYDNEY GOLD MINING COMPANY, County Harbour, recovered 455 ounces of gold from 510 tons of ore.

At FOREST HILL, McDonald & Copeland obtained 415 ounces of gold from 289 tons of ore.

Halifax County.

THE EAGLE MINING COMPANY, Salmon River, got 97 ounces from 143 tons of ore mined and milled.

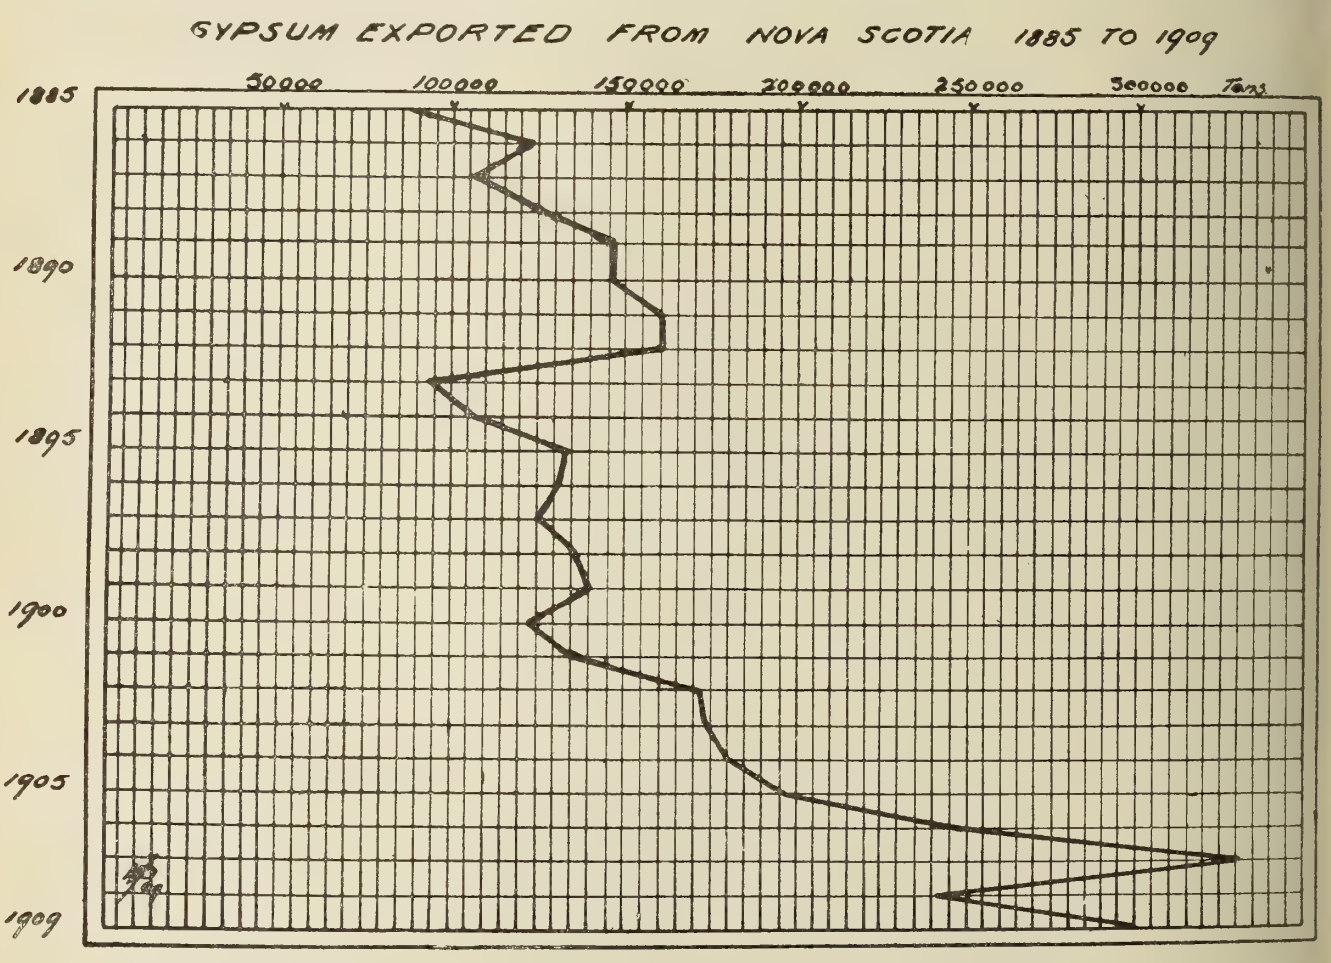
THE DOMINION MINING COMPANY, Tangier, obtained 62 ounces of gold from 180 tons of ore. This ore came from development work. A complete hydro-electric plant is now completed. Power is derived from dam on Tangier River and transmitted one mile. The mine will be worked on a larger scale this year.

CARIBOU GOLD MINES, Caribou.—About 40 men are employed here. From 1,055 tons of ore 824 ounces of gold were gotten.

M. J. O'BRIEN, Moose River.—The old Touquoy water-power mill was worked here on lease. 3,135 tons of ore yielded 539 ounces of gold.

OLDHAM STERLING GOLD COMPANY, Oldham.—From 940 tons of ore mined and milled, 2,710 ounces of gold were recovered, an average of 2.88 ounces per ton. (The average yield for the previous year was 4.53 ounces!) The shaft, an incline, is down 1,525 feet on the dip, or 850 feet vertically. At the shaft bottom the dip is 43 degrees. A Pelton water-wheel is installed to develop power for mill and crusher. The wheel is working under a 72-foot head, fed by a 14-inch pipe line.

THE OLDHAM MINING COMPANY, Oldham, won 2(ounces from 224 tons of ore. The ore was crushed the mill of the Oldham Sterling Company.



THE PETPESWICK MINING COMPANY, Lake Catcha, d voted the year to development.

THE CHESTER BASIN GOLD SYNDICATE, Gold River, o tained 307 ounces of gold from 791 tons ore crushe and milled.

THE UMACKE MINES & POWER COMPANY won 87 ounc from 100 tons of ore.

Queens County.

THE PONHOOK MINING COMPANY, Molega Barren mined 1,006 tons of ore, yielding 612 ounces of gol Crushing was done in the old Molega Mining Com pany's 10-stamp mill, which has been thoroughly over hauled. The hoist and mine pumps are operated by compressed air, piped 1,260 feet through a 3-inch line

Hants County.

THE EAGLE MINING COMPANY, Renfrew, obtained 4 ounces of gold from 180 tons of ore.

Victoria County.

THE GREAT BRAS D'OR GOLD MINING COMPANY, Middle River, milled 1,783 tons of ore, yielding 708 ounces of gold.

IRON.

During the year iron ore imports amounted to 666,050 tons, classified thus:

From.	Tons.
Newfoundland	639,527
United States	9,579
Spain	9,481
Norway	5,428
Ontario (Moose Mountain)	2,035
	666,050

The only iron ore mined in the province is credited to the Canada Iron Corporation. Their Torbook workings produced 12,000 tons from development entirely. None has been shipped.

The total production of pig-iron was 307,330 tons. The only producers were the Dominion Iron & Steel Company, Sydney, and the Nova Scotia Steel & Coal Company, New Glasgow and Sydney Mines.

COPPER.

LAKE COPPER COMPANY, Lochaber, Antigonish County. 14 men were employed. Shaft is now 290 feet deep. Drift from shaft bottom is 40 feet. An adit is in east 325 feet, connecting with No. 1 level west. A cross-cut is being driven north. Work has been discontinued in the shaft.

LEAD-SILVER.

Two small concerns, one near Boisdale, Cape Breton, and the other near Musquodoboit Harbour, are prospecting galena deposits.

GYPSUM.

The output of gypsum for the year was 299,045 tons. 600 men were employed. Eleven companies were in active operation. 25,000 tons were used in small local mills for the manufacture of wall cement, finishing plaster, plaster of Paris, etc. The remainder of the gypsum was shipped to the United States.

BUILDING STONE AND BRICK.

Four companies are reported as quarrying a total of 19,400 tons of stone (variety not specified). 22,000,000 bricks and 300,000 feet of drain pipe were manufactured by 17 concerns.

The records of the Provincial diamond-drill will be touched upon later.

PETROLEUM IN JAPAN.

According to a report in the "Deutsche Japanpost," a German contemporary dealing with Japanese affairs, a trade combination has been formed among the four large petroleum companies which supply oil to the Japanese market, the result being a rise of price of 10 sen per case. The companies referred to are the two Japanese firms, the Hoden Sekkyn Kaisha and the Nippon Sekkyn Kaisha, and the two American firms, the Standard Oil Company and the Rising Sun Company. The total consumption of Japan per annum is reckoned at 10,000,000 cases, of which the two American firms supply about 6,500,000 cases, the Hoden Company 2,300,000 cases and the Nippon Company 1,200,000 cases. The Japanese companies are so far only in the initial stage of their development and are only working oilfields in the Province of Echigo, but they also hold concessions in Hokksido, in the north of Japan, and in Formosa. Their oil is not of so good a quality as the American, but their cost of production is much less and their supply very constant, which enabled them to keep their price always a fraction below that of the American, which is handicapped with freight charges. By the agreement the American firms are instated in the right to meet about two-thirds of the Japanese demand for oil, while the Japanese firms are enabled to turn their attention with profit to the working of their hitherto untouched concessions. The only sufferer is the Japanese public, which now has to pay a higher price for its oil, whether it be the home or the foreign product.

MINING IN NICARAGUA.

(Written for THE CANADIAN MINING JOURNAL by an Occasional Contributor.)

The first recorded discovery of gold in the eastern division of Nicaragua, C. A., was made in 1886 by a Sumo Indian, named Josiah of Youga. Gustavo Schultz, a German merchant, then engaged in buying and exporting rubber from Nicaragua, was at that time prospecting for cinchoria in the forest on the banks of the Youga river. Here he met the Sumo Josiah, whose life he had saved.

Josiah asked Schultz what he was looking for. Schultz replied that he was in search of Peruvian bark. Josiah said: "Come with me and I will show you something better." He then took Schultz to Matice creek, a branch of the Principulca river, and turned over a flat stone, showing him a quantity of fine gold mixed with the black sand of the creek bed. Schultz immediately commenced work on the newly-discovered placer deposit and gathered the first riches, which, according to some interested parties, amounted to one ton of gold. This estimate of the production may be excessive, but it is known that Schultz was then in debt to the tune of $200,000. Shortly after he started placer operation on the Matice creek, he liquidated his account.

The gold of the Matice creek was derived from the erosion of an ore deposit, now known as the La Lus y los Angeles Mine. This is probably the richest mine yet discovered in this part of Nicaragua, though its monthly bullion shipments have not exceeded six or seven hundred ounces, owing to the poor management and defective surface equipment.

The "El Dorado" and "The Monte de Oro" mines, which are situated a few miles from the Matice creek, yielded considerable gold in the early days, but during the past few years have been worked in a desultory manner with negative results.

Some rich placer ground was discovered in the Cuicuinita district, situated twenty miles or so southeast of the Matice creek, about a year after Schultz commenced sluicing operation. This camp produced a large amount of placer gold, but so far no mineral veins have been found in Cuicuinita. The country east of Cuicuinita, drained by the Wowales creek and its branches, is not mineralized.

Bacan, which is a mesa or table-land, between the Cuicuinita and the Matice or Suina district, has produced about 2,000 ounces of alluvial gold, apparently derived from some small veinlets in porphyry.

In the year 1888 or 1889, a Jamaican rubber hunter named Grimmins, discovered the Constancia mine of

the Piz-Piz district, and a little later the Siempre Viva was located in the same mineral zone.

From that time several mines have been discovered in the Piz-Piz, and the district has been the centre of the mining activities of the Mosquito Coast.

Following the mineral discoveries in Piz-Piz, the Ocumwass district attracted prospectors with the location of the El Paraiso, the San Domingo, and some other mines of minor importance. The El Paraiso is a contact deposit between limestone and the Ocumwass shales. The main shaft is down about 115 feet and is the deepest in the country. The outcrop was very rich in places. The vein filling is chiefly calcite. The San Domingo is reported to be a clastic dike with high values in gold.

The La Luna mine is in the Ocumwass district and is a promising investment. Ocumwass has yielded a large amount of gold, chiefly as placer, or from the workings of some exceedingly rich verticals which paid to work in hand mortars.

The Minisota mine lies between Ocumwass and Piz-Piz. The gold here is an impregnation which has been traced in a northeast and southwesterly direction for about 15 miles. Scattered along the line are a number of mines such as Dos Amigos, Renco Viejo, Escondido, America, etc.

The Minisota is reported to have produced about $60,000 or $70,000 in gold, a large amount of which was recovered by washing a gold-bearing manta, which was formed by the leaching out of rich pockets in the impregnated porphyry.

In the Dos Amigios there is a manta which the owner claims to average $19.50 per ton in gold. The method of securing data is by drilling holes to bed-rock with a large auger, panning, sampling and assaying.

In the Bana Cruz district five or six veins carrying values in gold, have been denounced: the New America, the Union, the Sunshine and the Libertad . The samples from the New America assayed from $4 a ton to $80; the Union samples from $30 to $700 per ton, and eight samples from the Libertad from $3 to $79 per ton. Bana Cruz is reported to possess some water power, but there is no exact information on this subject. The mineral veins of the district appear to be faulted and shattered in places.

Several gold mines have been discovered in the Wawa district on the banks of the Wawa river and its branches, but the mineralization is, in general, poor; in fact the district may be classed as a zone of lean and sterile ores. There have been two notable exceptions, the Coco mine and the Tilba mine. Both of these mines produced considerable gold, and proved very profitable to their owners.

In the Wahawass district of the Wawa river some placer gold and platinum have been recovered by washing the creek beds.

The country rock is chiefly granite schists and porphyry. The Mother lode is on a contact between granite and porphyry and is covered in places with a manta ten to fifteen feet, which consists of a sintery mass of oxidized material earthy and black, carrying good values in free gold.

The gold in the Wahawass district was valued at $18 to $18.50 in the New Orleans Mint.

Cocoalya River.—Gold has been found in several parts of Cocoalya, but in general this may be considered a neglected section, as few prospectors have been through this part of the country.

Wanks River.—Miller's mine, on the Umbera creek, Wanks river, ranks next to Schultz's mines as a gold producer. Both placer and quartz gold have been produced in large quantities. Nuggets weighing from three to thirty-two ounces have been found in the wash which extended up the side of a hill. The overburden was fifty-eight feet in places.

The placer gold was evidently derived from the oxidization of a rich iron pyrite deposit carrying gold, which crosses the hill at right angles to the main pay channel.

In the Waspook creek of Wanks river an extraordinarily rich veinlet was discovered and worked by Juan Alresing some years ago. Lapierre bought the property in November, 1899, and in January, 1901, made the first shipment of bullion, time of development and equipment, therefore, being thirteen months. From the first shipment of January, 1901, to May, 1906, the bullion production of the Bonanza mine has amounted to the sum of $453,102.77. During the dry months of April and May when there was only water enough to run two or three 3 1-2 foot Huntington mills, there was a net profit on the mining operations of $6,350 for the two months, and the yearly gain amounted to 50 per cent. of the proceeds.

On November 29th, 1907, J. T. Clark arrived at the Morning Star Mine with supplies and tools. After considerable prospecting on the property, which is claimed to have exceeded the work done on any of the other mines in the vicinity prior to mill operation, Clark commenced milling with a three-stamp prospecting mill (250 pounds each) on November 15th, 1908. The time of prospecting and equipment was twenty months. In eight months' run with only a prospecting mill, the mine yielded bullion to the amount of $11,093.91, or 530 fine ounces gold and 255 silver as per mint returns.

On February 1st, 1905, H. B. Humphries bought the Santa Rita mine for W. D. Parker. On November 14th, 1905, Parker left the Bonanza mine. Later he returned and on July 24th, 1906, he commenced milling.

As per data from the "American" (the newspaper of Bluefields), dated December 19th, 1909, the shipments were as follows: The Bonanza mine, 1,586 ounces; Lone Star, 814 ounces; Santa Rita, 272 ounces; Siempre Viva, 712 ounces; Linda Ventura, 60 ounces; and other shipments, 450 ounces. This is but a part of some of the shipments, as a fair amount is shipped from other sources. However, it shows what has been accomplished up to the present, with quite inadequate equipment at the mines. The country has up to the present been barely scratched. Capital is needed and needed badly.

The South African Mining Journal, 19th Anniversary Number, March 12th, 1910.—In this very creditable issue our enterprising contemporary departs from its usual custom and incorporates a number of half-tones. Many highly instructive contributions appear. Not least interesting is a sketch of the history of the S. A. Mining Journal itself. An article on the development of mining during the past seven years in Rhodesia is also noteworthy. The total value of the mineral production of that country up to date totals £15,428,970. In this total gold is by far the largest item—£14,682,744. Coal comes next with £363,640. Then chrome iron ore, £139,099; silver, £113,906; lead, £61,774; diamonds, £39,115; copper, £21,266; tungsten ores, £10,930; asbestos, £2,875, and antimony £275. The total value of the mineral output last year was £2,808,123, of which gold made up £2,623,709. Much emphasis is placed upon the need of systematic geological surveys.

REPORT ON COAL MINES REGULATIONS RELATING TO SUBMARINE COAL AREAS.

(Submitted to the Government of Nova Scotia.)

By T. E. Forster.

Dear Sir,—I have, in accordance with the instructions which you gave when I visited Nova Scotia in August, considered the clauses in the Coal Mines Regulation Act relating specially to Submarine Areas, with a view to advising you as to their suitability to the conditions under which undersea coal is now being worked in the province. In order to enable me to do this, I visited, as you are aware, all the districts in which undersea mining operations are being carried on, and made underground inspections of various mines besides examining the sections of the strata exposed at different points along the coast. In this investigation I had the benefit of your own valuable knowledge and experience, as well as that of Mr. Fletcher of the Geological Survey, while I had further the opportunity of discussing with several colliery managers, questions in relations to the subject in hand. The ready and courteous spirit with which the information I required was everywhere imparted has been much appreciated by me. I now beg to report as follows:

The clauses in the Coal Mines Regulation Act relating to Submarine Areas are as follows:

54. (1) In the working of coal or stratified deposits in submarine areas, the following provisions shall apply:

(a) No submarine seam of coal or stratified deposits shall be wrought under a less cover than one hundred and eighty feet of solid measures. Provided, that the owner or lessee of any such area may drive passage ways to win the mineral to be wrought under a less cover than one hundred and eighty feet, but not less than one hundred feet of solid measures.

(b) A barrier of the mineral wrought, of not less than fifty yards, twenty-five yards on both sides of the boundary lines of every lease, shall be left unwrought between the workings of every submarine seam.

(c) Where there is less than five hundred feet of solid measures overlying the seam or stratified deposit wrought, the workings of every such submarine area shall be laid off in districts of an area not greater than half of one square mile, and the barrier enclosing each separate district shall not be less than thirty yards thick, and shall not be pierced by more than four passage ways having a sectional area not greater than nine feet wide and six feet high. Provided, that the inspector may, if he deems it necessary, permit the said passage ways to be driven with a cross section, not exceeding sixty square feet.

(d) No district shall have its length when parallel to the general trend of the adjoining shore greater than one mile.

(e) A proposed system of working the mineral in each submarine area shall, before work is commenced, be submitted to and approved of by the inspector, and no change shall be made in such approved system without the written sanction of the inspector.

(f) The opening of a new lift or level in a mine already working in a submarine area shall be deemed the commencement of a new winning within the meaning of this section.

(2) The owner, agent or manager of any mine to which this section applies, who contravenes or fails to comply with any provision of this section, shall each be liable to a penalty not exceeding one thousand dollars, and if the offence complained of is continued or repeated after a written notice has been given by the inspector to such owner, agent or manager of any such offence having been committed, the Supreme Court, or a judge thereof, whether any other proceedings have or have not been taken, may, upon application by the Attorney-General, prohibit by injunction the working of such mine. Provided, that the Commissioner may waive or modify any of the provisions of this section when, on the report of the inspector, it appears to his satisfaction that valuable coal areas cannot be otherwise wrought or mined.

R. S., c. 19, s. 52; 1903-04, c. 2, s. 7.

Before discussing in detail the above regulations, I think that possibly it may be of interest and advantage to give a short account of the system under which the working of submarine coal areas is regulated elsewhere.

In this country the undersea coal is the property of the Crown, from high water mark for a distance of three miles seawards, though there are cases in which possession of the coal under the foreshore, between high and low water-marks, is vested in the owner of the coal under the adjacent land where he has been able to prove his title to it either by virtue of a direct grant or otherwise. The leasing of the undersea areas is conducted by the Office of Woods and Forests, assisted by a mining engineer who deals with all technical points relating to the method of working, controls the submarine workings, and looks generally after the interests of the Crown as owner of the minerals, but has nothing to do with the administration of the Mines Regulation Act, which is carried out in the ordinary way by the Inspector of Mines. In other words, the Office of Woods and Forests acts in the same way as any private owner of minerals in this country, and makes such conditions as it thinks fit as to the method of working, to which objection can only be taken by the Inspector of Mines under the Mines Regulation Act in the event of his considering it to be unsafe.

There are no clauses in the Coal Mines Regulation Act dealing specially with submarine areas, as in Nova Scotia, any special provisions as to working being included in the several leases. In framing these conditions it has always been the practice, and I think a sound one, to consider the special circumstances of each letting, rather than to attempt to regulate the whole on a hard and fast basis.

At the present date the leases which are issued by the Office of Woods and Forests generally contain clauses restricting working under a specified cover and providing for the workings being controlled by their mining engineer. The limit of working is, I think, usually placed on what may be termed the "safe side," but as the workings are opened out and information as to the surroundings and experience of the effect of operations is gained, there has, in my experience, been no difficulty in obtaining any reasonable variation of the terms of any lease which the particular circumstances of the case appeared to warrant. I have had as a lessee, a long experience of the system, and I am of opinion that, under it, great advances have been made and large areas have been worked which would otherwise have been abandoned.

So far as I am aware, the only case in which definite regulations for the working of undersea coal (similar to some extent to those in force in Nova Scotia) have been established is that of New South Wales. I have a personal knowledge of this locality, having visited it on two separate occasions, and having acted for a considerable time as consulting engineer to a company engaged in working its undersea coal. Experience obtained in this way enables me to point out that the regulations in question were framed with a view to meeting the special conditions occurring in the vicinity of the Hunter River estuary, where the presence of extensive alluvial deposits overlying the principal seam of coal, combined with its shallow depth, rendered it necessary to ensure special precautions being taken. For this reason, I consider that these regulations generally cannot be taken as forming a guide to those which would seem to be necessary in the case of the Nova Scotia fields.

The provisions contained in the Nova Scotia Mines Act were, I understand, drawn up about the year 1877 by Mr. H. S. Poole, then Chief Inspector of Mines. They appear to have remained unaltered (except for one variation on a matter of detail) since that time. In the report of the Department of Mines for the year 1877 Mr. Poole discussed at some length the question of submarine mining in Nova Scotia. The information contained in this report has proved of great interest and value to me, throwing light as it does on the nature of the evidence on which Mr. Poole founded the regulations, and the opinions which were held at that date by various persons interested in undersea mining. I would point out that the thirty years which have since elapsed have provided a large amount of additional experience attended by, in some respects, a change of views.

I will now proceed to remark in detail on the various provisions contained in the Act:

54. (1) (a) Provides that no undersea workings shall be carried on at a less depth than 180 feet of solid cover, but gives power to the lessee to drive passage ways for the purpose of winning the deposit only, under a cover of not less than 100 feet.

Although it is true that, both in this country and in New South Wales, workings have been carried on successfully, under special precautions, at less depths than 180 feet, I am of opinion that having regard to the general nature of the beds overlying the seams in the various districts adjoining the seaboard in Nova Scotia, it would not be advisable to alter this regulation. It must always be a difficult, if not an impractical task, to ascertain the exact thickness of the "solid measures," and I think therefore that a considerable margin of safety should be provided. In the case of passage ways to be driven under a less depth than 180 feet of solid cover, I assume that, if it should be thought necessary and judicious to reduce the 100 feet limit in any particular instance, the Commissioner could, under sub-section 2, sanction such a proceeding.

(b) Provides that "a barrier of not less than 50 yards, 25 yards on both sides of the boundary lines of every lease, shall be left unwrought between the workings of each submarine seam."

Section 208 of "The Mines Act" 1892, in which I presume that the term "land covered with water" includes submarine areas, provides that a barrier of 25 yards is to be left "within and along each of the boundary lines" of any submarine lease. This is in effect the same as the regulation quoted above, but, I think, expresses the nature of the reservation more clearly, and I would suggest that it might possibly be advisable to alter the clause in the Mines Regulation Act so as to make it correspond with that in the Mines Act.

It may happen, I think, that with deeper mining or under special circumstances, wider barriers may be required, so that it seems to be a matter for consideration whether power should not be given to the Commissioner to require such extensions, if considered necessary.

(c) Provides that, where there is less than 500 feet of solid cover over the seam worked, the workings shall be laid out in districts of an area not greater than half a square mile, each district being enclosed by a barrier not less than 30 yards in thickness, which shall not be pierced by more than four passage ways of a sectional area not greater than 9 feet wide by 6 feet high, with a modification to the effect that the inspector may, if he thinks it necessary, permit the cross section of the passage way to be increased to 60 square feet.

(d) Restricts the length of any district when parallel to the general trend of the adjoining shore line, to one mile.

(e) Requires the submission to the inspector of any proposed system of working, and his approval of the same before work is commenced, as well as his sanction to any change being made in the approved system.

(f) Provides that the opening of a new lift or level in a mine already working shall be deemed the commencement of a new winning within the meaning of the section.

I have thought it better to consider the above regulations together, as they seem to comprise those which relate expressly to the methods under which the coal is to be worked or points in connection therewith.

The first two provide for the application between the lines of 180 and 500 feet of cover, of a system which is generally known as the "panel system." Under this the area to be worked is divided into districts or "panels" surrounded by barriers through which as few holdings as may be considered absolutely necessary are made. The dimensions of these places are restricted so as to enable dams to be placed in them in case of any inburst of water occurring in the panel in which they lead, with the object of shutting off the district and preventing a general flooding of the workings. This system has been practised to a considerable extent in this country in the case of workings at moderate depth, but I think that experience has shewn that, while it presents many disadvantages, it offers in reality little, if any, real security. The restrictions as to the number and dimensions of the places communicating with the panels cause great inconvenience both in the matter of haulage and ventilation, while the loss of coal due to the barriers left is considerable. On the other hand, it is very seldom that the conditions of the strata surrounding the drifts are such as to render any prospect of dams, likely to be of an effective nature, being capable of being erected. Under these circumstances—and they are such as I consider apply in the same way in Nova Scotia as here—I do not think that any importance can be attached to this method of working, but that it is better to rely on the pillars left for the support of the roof being properly proportioned with a fair margin of safety and a careful restriction of the width of the working places and disposition of the same.

I am of opinion, therefore, that no advantage can be obtained by the retention of these provisions, and that their elimination from the regulations would not lessen the security of the mines, while it would, on the other hand, lead to a saving of coal and give improved facilities for working. Under the regulations the system of working below the 500 feet line is unfettered, though subject to the approval of the inspector. I think that the same condition should apply wholly, as it already does in

part, to operations carried on between the 180 to 500 feet lines, or, in other words, that the system of working should be entirely under the inspector's control, as it appears evident that, in any case, some controlling authority must eventually take the responsibility of regulating workings of this description. I am strongly of opinion that the conduct of undersea workings cannot, generally speaking, be advantageously provided for by hard and fast rules, and that a careful consideration of the circumstances of each case, guided by experience gained in the gradual development of operations, is the proper system to be pursued in such cases.

As to matters of detail I would make the following suggestions:

1. In clause (e) I think that it should be provided that the approval of the inspector in the first instance should, as in the case of any alteration, be in writing.

2. I am of opinion that provision should be made, either in the Mines Regulation Act or in the leases, that, where any workings are carried on upon the long-wall system, an exploring drift shall be driven fifty yards at least in a seaward direction in advance of such workings so as to prove the existence of any faults or dislocations, until it reaches the barrier required to be left.

3. I think that surveys and levellings of undersea workings should be made every three months, and that the levels together with the depth of cover should be marked upon the working plans at specified distances along the lines of all main roads and round the faces of all workings approaching the 180 feet line of cover. Soundings should also be taken at reasonable distances and recorded on the plans.

I trust that you will let me know if there are any points on which you require further information or explanation, in which case I shall be very pleased to do my best to afford it.

Yours faithfully,
(Sgd.) T. E. FORSTER
Newcastle-on-Tyne, October 22nd, 1908.

HIRAM DONKIN, ESQ.

GRANBY MINES, BOUNDARY DISTRICT.

The publication of a statement to the effect that the ore reserves of the Granby Mines, in Phoenix camp, Boundary district, are within measureable distance of being exhausted has caused great surprise and, to many stockholders, much monetary loss. Whether there is or is not good reason to believe that mines heretofore regarded as having an abundance of ore, sufficient to supply the company's reduction works at full capacity for a much longer period than can be done if there prove to be only six million tons of ore available, as now stated, is a question that can only be determined by fully qualified mining engineers and that after a most exhaustive examination of the property. There are some circumstances, though, which would appear to make it quite reasonable to ask whether the directors of the company and their late local manager are in any way to blame for the present disastrous situation. At this time it may be of interest to point out that the management of the Granby Company has not at any time, so far as has come to my notice, made public information that would throw doubt on the general belief that the reserves of ore in the company's mines were not large and equal to all demands likely to be made upon them for a longer period than it is now suggested they will last at present rate of production. Without going back to the very optimistic assertions that some years ago were occasionally made, attributing to the Granby Company possession of mines which with an output of one million tons a year had ore enough to last at least one generation and probably two, it is reasonable to ask how far statements made within the two years last past were or are dependable. For instance, Mr. A. B. W. Hodges, until quite recently local manager of the company, stated at a meeting of the Canadian Mining Institute, held in Parliament Buildings, Victoria, in September, 1908, on which occasion there were present a number of influential mining engineers and geologists from Great Britain, continental Europe and Eastern Canada, that "from 10,000,000 to 30,000,000 tons of these low-grade ores are in sight in the Boundary district." Again, he said: "We have in one of our mines 10,000,000 tons of good ore." In the "Souvenir Number" of the Canadian Mining Institute Quarterly Bulletin, Mr. H. Mortimer Lamb, secretary of the Institute, when describing the visit to the Granby mines, wrote: "There is said to be approximately 20,000,000 tons of ore in sight." Last August a New York firm, which makes it a practice to send out "information obtained from what we regard as reliable sources, and believe to be accurate," advised its clients and others as to the Granby Company's ore reserves, as follows: "Exact figures on the ore reserves are not available, but according to the management the tonnage is placed at between 12 and 15 years' supply on an annual consumption of 1,000,000 tons." Further, in its issue of November 27, 1909, the Phoenix "Pioneer" published an interview with Col. N. E. Linsley, of Spokane, Wash., whom it credited with saying, in part: "About March 26, 1898, I made the first report on the Old Ironsides for Mr. Jay P. Graves. Then, on February 12, 1903, I made a complete report on the properties of the Granby Consolidated Mining, Smelting & Power Company, Limited. At this time the Granby was a going concern, mining and treating 1,600 tons of ore daily, with 8,500,000 tons of workable ore blocked out and 14,000,000 tons more reasonably in sight. Altogether, about 5,000,000 tons have been mined at the Granby's Phoenix properties and treated at the company's smeltery since then, and still at the present time, from a cursory examination, there is more ore in sight than there was then." These and other statements to a like effect have been permitted to go uncontradicted by anyone in authority in connection with the company. Of course it may be claimed by the directors and officers of the company that it is not incumbent on them to contradict statements published without their authority, but even if this be so there are other circumstances, and for which they are responsible, that have given stockholders and the public generally a feeling of security. For instance, the expenditure on constructive account during the past two years of a sum stated to have been about $250,000, and the recent issue of 13,500 shares of treasury stock at $85 were surely intended to give stockholders the impression that the company might be expected to have before it a long life of profitable operation. Perhaps, after all, this impression is warranted by actual conditions. It is not well to take it for granted that the recent panic and consequent heavy fall in the market price of shares in the company was fully warranted. Until assured on thoroughly reliable testimony that there really is reason for serious concern as to the future, prudence suggests that the statements of Messrs. Jay P. Graves, vice-president and general manager, and W. Yolen Williams, consulting engineer, be given due consideration. A published telegram from Mr. Graves says: "I have not

visited the mine personally for about 18 months, but according to our employees there has been no change in the mine during that time for better or worse," while to Mr. Williams is attributed the following assertion: "No important developments of any kind have taken place in the mine for two or three years. I mean by that that no new knowledge has been gained as to the extent or limit of the ore bodies." Mr. Yolen Williams directed the opening of the mine during eight years, 1896-1904, so that he was fully informed as to conditions prior to relinquishing the active oversight of development work. Whether the extraction of about five million tons of ore since Mr. Hodges took charge of the mine exhausted all the reserves of which Mr. Williams knew, is not apparent, but there is this fact to be kept in mind—Mr. Williams has a high reputation for long experience as a practical miner, for undoubted ability as a mine manager, and for strict integrity as a man, so that if he shall have carefully examined the mines lately, his judgment and opinions should have respect until such time as there shall be adequate evidence to prove him wrong. Incidentally, it may be mentioned that the aggregate tonnage of ore extracted from the Granby mines to date is about 6,045,000 tons, of which quantity about 1,650,000 tons have been produced since September, 1908. If Mr. Hodges was justified in then claiming that IN ONE of the company's mines there was "10,000,000 tons of good ore," it is plainly evident that there should remain considerably more than 6,000,000 tons IN ALL of the Granby mines. The official explanation of the situation by the directors is being anxiously awaited, and if this shall not be clear and satisfactory it would seem that there should be close enquiry into all the conditions, and an exhaustive examination of the mines by independent and competent engineers.

Storage Battery Electric Locomotives Handling Copper Ore.

By Frank C. Perkins.

The accompanying illustration shows a novel type of electric storage battery locomotive designed for industrial service handling copper ore and ingots at Constable Hook, N.J., for the Oxford Copper Company.

There are many situations where the trolley type of electric locomotive is undesirable on account of the appearance of an overhead trolley wire system. In many cases the fire risk is also serious through the sparking of the trolley, this risk being eliminated when a storage battery locomotive is utilized. As it is able to take curves of 12 feet radius, every part of the work is made accessible by this type of locomotive, even where the buildings are irregularly placed and close together.

The motors are of the enclosed type and the storage batteries require no attention during working hours, while it is maintained that the cost of operation for haulage is far less than with animal power. The narrow gauge locomotive weighs 4 tons and is designed for a track having a gauge of 21 1-2 inches. This storage battery locomotive measures 70 inches high and 56 inches wide over all, the total length being 12 feet. Only when the locomotive is in service is electric power used, all cost for electric current ceasing when the controller handle is thrown to the off position.

There are two independent electric motors employed which are connected in series or in parallel, allowing a speed of from one to four miles per hour. At low speeds the motors give a great starting effort with a minimum consumption of electric current and the storage batteries have a capacity such as to give a range of action for the locomotive of ten hours in ordinary service. This narrow gauge electric storage battery locomotive will haul 50 tons on a level and 25 tons on the one per cent. grade, while on a two per cent. grade it will handle 15 tons without difficulty. The capacity decreases from ten tons to seven tons and five tons respectively on grades of three per cent., four per cent. and five per cent. A direct current of 110 volts or 120 volts is used for charging the storage battery at regular intervals. The system of charging is so thoroughly safeguarded and simple that any careful workman can be entrusted with this work without technical knowledge.

A Discussion of Leopoldo Salazar's Paper on the McArthur-Forrest Cyanide Patents in Mexico; and the Lessons to be learnt from the History of this Subject.

By John Malcolm Nicol.

(Proceedings of the Mexican Institute of Mining and Metallurgy.)

Mr. Salazar's very interesting paper on the McArthur-Forrest Cyanide Patents, raises a number of questions of the whole subject of Patent Law, and before I can attempt to answer some of the questions which he propounds, or discuss the problems which are brought to light by the historical part of his paper, I think it will be advisable to give clear definitions regarding patent law and inventions.

As I understand it, the first purpose of the patent law, based on the human sense of justice to "Render unto Caesar that which is Caesar's," is to insure that society gives to an inventor a just and fair reward for the benefits which his inventions give to society.

The second object is to develop a stimulus which will tend to make more men take up the drudgery, and heavy mental strain, of solving the problems that are continually arising from the ever-growing demands of the industrialism of modern civilization: this stimulus being the commercial reward resulting from the ownership of a valuable patent.

It is only just beginning to dawn on legislators that the industries and manufacture resulting from modern inventions are of great economic value to commerce, and national income, and hence the third object of the patent laws of a nation may well be, to not only concentrate within her territory men of brains and intellect, but to obtain a share of the wealth resulting from the manufacture of their inventions, and with this object in view the new English patent law requires that a regular manufactury be established for the production of a patented article or else the patent becomes null and void after a few years.

The next definition that we require, is one that will give us a clear understanding of the words, discovery, research, invention, and design, in the sense in which they should be used in relation to the patent law.

I feel and I think, that many of our learned friends present will agree that a new word is needed in the English language to define the difference between a "chance discovery" and a "discovery" that has been made, by definite research work, leading up to some phenomena, or substance whose existence was deduced but whose qualities were unknown.

I therefore take the liberty of coining a word to designate a discovery which is the result of deliberate research: let us call it a "pruvery" and reserve "discovery" far chance finds. These two words have their principal application to the natural phenomena of physics and processes based thereon.

The former class of discovery is interesting and may be invaluable to humanity, but deserves reward only in relation to the associated work of the discoverer; the latter class is evidence of the finest type of intelligence of the human race; and although the "pruvery" may only be of scientific value and industrially worthless, yet it is worthy of the highest honours and reward that humanity can confer on the demonstrator, as it leads to unknown potentialities in the development of human intellect.

As examples bearing on the question of patent law I will cite the following:—Edison's chance "discovery" of the phonograph, and Ramsey and Raleighs' "pruvery" of Argon. Edison was working with a German assistant in his laboratory, experimenting with an instrument for recording the vibrations of a musical note. He had constructed one with a wax-coated cylinder driven by a small electric motor. By chance the assistant reversed the drive, and the impression on the wax cylinder passing under the disc reproduced the notes. The German, with Teutonic bluntness, said, "my God, she speaks." Thus Edison discovered by pure chance the phonograph. He subsequently "invented" the needles, discs, etc., and "designed" the mechanism as a whole, which made the phonograph a commercial success.

The discovery of the phonograph resulted in a valuable patent, which gave great reward to the owner, and yet the discovery in itself deserved little credit, and, while it is of occasional use commercially, it is otherwise merely a toy.

The "pruvery" of Argon could not be patented and had no commercial value, and as far as I am aware, brought no financial reward to Ramsey or Raleigh, and yet the demonstration of the existence was the result of patient mental effort, and was of great value to the intellectual development of the human race, because it was an infallible proof of the absolute accuracy and reliability of our modern scientific methods of deductive reasoning.

An "invention" consists of finding a means of applying a process to an industrial use, or of planning an apparatus for the working of a process. An "invention" must in every case be an original idea which has never been executed, or a combination of known "ideas" in such a novel form, or for such original purpose, that it virtually forms a concrete conception in itself.

A "design" in mechanics consists of grouping together known principles, and designs, to produce a required effect. The border line between "discovery," "pruvery," "invention" and "design" is interlaced by each, and perfect definitions are difficult and I know that those that I have given are far from complete but they will serve my purpose for the present.

The field is now clear for me to discuss the questions and problems of Mr. Salazar's paper.

First, the discovery or "pruvery" of Hagen in 1806 revealed a chemical phenomenon; the action of cyanogen on gold. It was not in any sense an invention. Even the work of Simpson in 1885, for which a patent was granted, barely merits the title of invention, and with regard to Mr. Salaza's fundamental question, "can a process be considered as new when it has been proposed but has never been put in practice with industrial ends in view?" I would emphatically state that the application for industrial ends bears no relationship to its claims for novelty. A process that has been once proposed or demonstrated is not new. A man who takes a known and demonstrated process and applies it may be doing a very meritorious act, and may demonstrate an industrial utility that was unknown before, but he is not an inventor, and should not be granted a patent. We must find other means of rewarding him. Neither

can the "amount of dilution" of a chemical process be considered ground for a patent, for the amount of dilution is a variable function, known to be common practice to all forms of chemical processes. On this point I heartily agree with Mr. Salazar when he states "that the restriction is unscientific in principle."

In the case of the McArthur-Forrest patents, it seems clear on the basis of the above argument that they did not make any invention at all. They merely designed plants which made possible the application of known chemical phenomena to industrial purposes.

They may have invented numerous mechanical details for apparatus to carry out the above process, but these had no relation to the patents which were granted.

It therefore seems that if patents are to be allowed only for novelty and invention, that a patent should not have been granted, and yet there is no question but that the early success of the cyanide process, and the resultant position of the industry, was primarily and largely due to the ideas, the brains, energy and courage of the McArthur-Forrest combination.

Ethically, then, the patents should not have been granted, and yet if it had not been for the assumed guarantee of a monopoly resulting from these patents, the capital might never have been invested, and the experiments and working tests made, which have resulted in world-wide benefits from the modern cyanide process.

On the general principle that it "pays a nation" to stimulate brain energy, and to assure a suitable and just reward to the intrepid investigator, experimenter, and demonstrator, it would seem that a law is needed that could grant a monopoly that is not a patent, and not a concession for just such cases as these; and as the granting of such a monopoly would have to be certain and independent of reversal by the courts, it is evident that "a priori" search would be necessary.

It seems, therefore, that four distinct evidences of human intelligent effort have to be dealt with in relation to the patent law.

First: The scientific research worker, whose discoveries or "pruveries" either directly or indirectly are of inestimable value to human industry; yet little, if any of their work is subject to protection and reward by patent, their only recognition being that of scientific societies, who give gold medals, and occasional prizes.

Second: The recognized body of inventors, men who seeing the demand for a machine or process to meet an industrial requirement, "invent" a novel "method" for the solution of the same. These are more or less protected and encouraged by the various existing patent laws.

Third: Those who, by the aggregation of known principles and by the perfection of plant design and careful test and demonstration, create new industries from known, but untried, or half developed processes. These men are probably one of the most valuable assets that a nation can have, and yet they have never been recognized as a body, and no legislature has ever attempted to create laws which would in justice protect and stimulate this class of human endeavour.

Men under this heading frequently try patenting some trivial part or adjunct, a procedure which is generally a failure.

Fourth: We have the purely commercial type of man who undertakes to establish a well-known process, or recognized industry, in a new locality where commercial success, and financial reward, are uncertain, but where the establishment of the industry is of great national economic importance. This man is amply protected by the granting of concessions which give him an exclusive monopoly as a reward for his endeavours and the risks he takes.

I only draw attention to this fourth class for the simple reason that it might be supposed that such cases as McArthur-Forrest, failing to obtain adequate protection from patents, might obtain reward for the speculative investment in experiments and demonstrations by this means; but for reasons which will be self-evident from my further arguments, it will be seen that a separate law is really required to meet the cases under the third heading.

Of course the work of each of these groups is co-related and merges insensibly one into the other. But I think that my definition and meaning is sufficiently clear, and will be generally accepted. The first, second and fourth, I know, are generally accepted, and to make my statements regarding the third class clearer I will name some typical examples: (1) The application of the cyanide process to metallurgy. (2) The development of step-reduction, crushing and trituration as a process. (3) The perfection of the mechanics and dynamics of the cyanide process. This latter is a particularly interesting example, as although numerous patents have been taken out there is hardly one of them which is "ethically" valid, and yet the mining world is reaping a rich harvest from the work of many men who have devoted much time and study to the application of known principles and to the perfection of design. Under this head I include the various vacuum filters and air agitation tanks, classifiers, pulp thickeners, etc. (4) The application of dredging to gold placer mining, etc.

Against this list, which could be continued almost indefinitely, we find that in some cases the patent law grants sweeping monopolies for veritable "tricks of wit," which enables the holders to really hinder industry and to reap a rich and undeserved reward. The best example I know of this was the basic combination patent on automobiles, granted in the United States.

It appears to me that one of the lessons to be learnt from Mr. Salazar's paper is the necessity of being able to properly classify the nature of the work that has been done by a so-called "inventor" when he presents an application for a patent. To quote, Mr. Salazar says: "When a process which, on account of its lack of novelty, has everywhere been pronounced faulty in the eye of the law, nevertheless works such an extraordinary revolution in an industry, it is reasonable to suppose that there are circumstances which have escaped the legal mind, and these circumstances are in my opinion, of a purely industrial character, and should, therefore, be defined by those engaged in the industry."

I beg to disagree with Mr. Salazar. I do not think the circumstances are purely industrial. It appears to me that the legal mind has overlooked the difference in status between the classes 1, 2, 3 and 4 which I have enumerated. The function of the law in these cases is to insure to a man the enjoyment of something that is his, and for this reason it is ethically doubtful if the patent law should force a man to manufacture something that is even more essentially his own than the possession of land. Or that it has the right to dispossess him of a monopoly once granted any more than it has the right to dispossess a man of the title to land. In fact, the latter procedure, which is not practised for the public good, except in exceptional cases, is more logical and just than the former, which is recognized and prac-

sed by all nations. But then land owners and not ngineers, were the framers of our laws.

Here, then, are the problems which are brought to ight by Mr. Salazar's paper and by my discussion:

(a) How many classes or divisions of the inventor's vork (in the broadest sense) do we have to consider? b) What specific thing is presented by each class that an be considered as deserving of judicial recognition nd legal protection? (c) To what extent and for what eriod are we to grant monopoly (if any) for the purose of reward and stimulus of each class? (d) How an we give to individuals right and title to monopolies without interfering with the possible future rights of another individual or the community at large? (e) How can monopolies be given which will stimulate without retarding industry, and thereby be of national benefit?

Mr. Salazar implies that he would welcome not only discussion, but suggestions, and I will therefore take the liberty of attempting to give some answers to the above. But in doing so I will assume that the tendency of the modern law maker is to consider the welfare and interests of the majority before the right and title to monopoly of the individual, and will therefore postulate that the purpose of the patent law is only to grant sufficient monopoly to stimulate and reward endeavour and to regulate the relationship between the owners of patent monopolies and the general public.

We then have to consider the best method of dealing legally with: First, Research workers or pure scientists; second, inventors proper; third, designers and demonstrators; fourth, industrial organizers.

Dealing with the first class, the men who devote their lives to this work as a rule are jealous of honour, but care little for financial reward. They only need money as a means to an end. The type, while being commercially inefficient, is yet of immense value to commerce. Therefore, commerce, industry, and especially monopolies resulting from patents, should be directly taxed for the support of scientific institutions, and the necessary research workers.

Dealing with the second class, it seems only logical that every assistance should be given to the inventor, so as to stimulate him to endeavour, and with this end in view the cost of patenting should be made very low, and means of registering a provisional patent should be provided. A well-equipped institution with every facility for research on former and expired patents should be provided, the costs to be maintained from a tax on successful patent monopolies, and not from the patent fees. In fact, I believe registration should be preferably free. The inventor naturally wishes to obtain by his patent a monopoly which has a commercial value. Therefore a patent once granted should be final, and not subject to reversal by the court, except for proven theft of ideas, or fraud. This necessitates "a priori" research of a very thorough nature.

Nearly every invention is the forerunner of others, and numerous improvements immediately follow. It is, therefore, very necessary to grant a monopoly on such lines that it does not hinder industry or prevent other inventors from manufacturing their improvements. The general public the world over are failing to derive benefits from numerous valuable inventions and discoveries which are lying idle, and locked up, being held to protect some industrial monopoly which is operating inventions of an earlier date.

Bearing this in mind, I would suggest that any person might manufacture, or sell an invention once patented and published, or incorporate another man's patented invention with improvements of his own, without the permission of the inventor, providing only he makes application to the patent office and pays a royalty to the inventor.

All royalties would be based on a percentage of the sale value of the machine, subject to law, and not upon the whim or fancy of the owner of the patent. The effect of this would be to protect and encourage inventors and to prevent financial interests holding idle patents for industrial ends to the detriment of the public welfare.

Any experimentor might write articles or publish or discuss data regarding his experiments or build experimental machines, apparatus or processes, without invalidating his rights to apply for patent protection, providing he makes application within two years.

The publication of data under his name being taken as proof of the genuineness of the invention being his. No royalties can be claimed while a patent is pending and until it has been finally granted.

Provisional patent applications could be amended during the period for which they are granted. Final application would be unalterable, except at the recommendation of the patent authorities. Inventions might be roughly classed as follows: (1) Basic; (2) combination; (3) secondary, i.e., improvement following original ideas; and (4) transfer, the latter being the transferring and adapting of idea from one industry to another.

When search, made by the patent office, shows that an idea brought forward by a person claiming invention is not novel, but has been known of in some form or another before, but has never been actively made use of, owing to the fact that no one has been found who has the courage and energy to test, prove and demonstrate it, a patent should be denied; but a monopoly of another form might be granted, carrying with it the necessity of establishing a demonstration on an industrial scale, and, if shown that it was an improvement in the art and a benefit to industry, the right to collect from others a royalty on a very moderate percentage basis (to be fixed by the patent office), should be allowed. This would cover the third class, and just such cases as the McArthur-Forrest, and at the same time would not be in the nature of an absolute monopoly and a restriction to future trade, such as often results from the granting of exclusive concessions under the fourth class.

The Mining Magazine, March, 1910.—In a leading editorial the Mining Magazine, while speaking in highly respectful terms of the officers and members of the Mining and Metallurgical Society of America, argues that since this organization has a membership of only 160, it has little right to speak for the thousands of engineers, metallurgists, and geologists of America. It is characterized, so in effect continues the Mining Magazine, by a spirit of false exclusiveness. "The attempt of a fortuitous aggregation of individuals to sit in judgment on the members of a profession that includes thousands of men of varying education and occupation has failed utterly." The generous policy of the American Institute of Mining Engineers is, in our contemporary's opinion, much the better of the two.

During 1909 the Rio Tinto Copper Company paid dividends at the rate of 60 per cent. net. The rate for 1908 was 55 per cent. net.

ZINC MINING IN BRITISH COLUMBIA.

The recent authorization by the Canadian Parliament of an expenditure of $50,000 in investigation by the Dominion Department of Mines of processes for the reduction of zinc ores and making experiments in connection therewith, recalls the fact that the question of how the zinc ores of British Columbia can be turned to profitable account has had the attention of owners of mines in the Slocan district, in which zinc occurs in quantity, from time to time during the past six years, and to a smaller extent for a longer time.

Investigation of Zinc Resources.

Early in 1904 an organization, consisting chiefly of owners and managers of silver-lead-zinc mines situated in Slocan district, known as the Associated Silver-Lead Mines of British Columbia, instructed its special committee to memorialize the Dominion Government to engage a high authority on zinc and its treatment to investigate and report on the zinc ores of the Kootenay district. This proposal was endorsed by the Associated Boards of Trade of Eastern British Columbia. In connection with this movement, Mr. A. C. Garde, then resident manager for the Payne Consolidated Mining Co. owning the Payne mine, near Sandon, Slocan district, prepared and published a statement outlining the benefits to be derived from fully investigating the zinc resources of British Columbia as to their extent, value, character, etc., and giving much information relative to the occurrence of zinc in association with silver-lead ores in mines in Slocan district and, incidentally, a brief summary of places elsewhere in the province at which zinc-bearing ores had been found.

In the course of his review, which was a lengthy one, Mr. Garde gave the following information: During ten years to that date zinc ore had been known to occur in British Columbia, especially in districts where silver-lead mining had been carried on, but only in 1903 had much attention been paid to their economic features. The presence of zinc in excess of the smelter's limit of ten per cent. had involved the ore being penalized by the smelters at a rate of 50 cents per unit. It had been found in a number of Slocan mines that lead in large measure gave place to zinc, or that the two metals were so intermixed that separate processes for their recovery, respectively, had had to be adopted. This led to the finding of a market for zinc, much of which had previously been run to waste when concentrating the silver-lead ores. Many difficulties still confronted the mine-owners; some ores were of a complex nature, some had low values in silver, or there were obstacles to effective concentration and in the high cost of transportation. The establishment of zinc reduction works was, therefore, an evident condition to the profitable working of the mines in which lead-zinc ores occurred in quantity. But capitalists would not expend money in erecting and equipping local reduction works until they had been satisfied that the character and extent of the available zinc ores would warrant them in doing so; hence the urgent necessity for a full investigation by a competent authority of the zinc resources of the province, and the conditions attending their utilization. That such an investigation would result favourably there was little doubt, for it was known the zinc resources were extensive. The resultant benefits would not be restricted to zinc mining, for it was believed that in exploring for zinc ores large bodies of lead ores would also be discovered, the two metals occurring in the province in close association.

The varying physical features of the zinc ores of the different districts puzzled both the miner and the metallurgist in one respect, namely, that of the wide difference in the value of their silver contents, some ores carrying only about 6 oz. per ton while others ran high in silver. Within a radius of ten miles of Sandon, though, the average silver content of zinc ores, was estimated at about 25 oz. per ton of 50 per cent. ore. Emphasis was placed on that fact, for the reason that the prevailing opinion was that Slocan ores contained a far higher average in silver, and that until such time as the smelters should be able to pay for more than three-fourths of the silver it would be better to leave in the mines ores running high in that metal, looking to the recovery of a higher percentage of it being eventually made practicable.

An important consideration brought out was that, apart from their silver contents, the zinc ores of British Columbia were worth mining for only the zinc in them. It was believed that there exists in the province an unlimited quantity of zinc ore, suitable for both spelter and zinc oxide production. The zinc mining industry, therefore, should not be hampered by the fact that highly argentiferous zinc ores also occur. These should be regarded as exceptions to the rule and should not be permitted to interfere with the utilization of the large deposits of strictly zinc-bearing ore workable for their zinc contents only. One of the chief objects in view in persistently inviting public attention to the zinc ore deposits of British Columbia was to secure a general realization of their extent and considerable value. Zinc smelters in both the United States and Europe had already awakened to the potentialities of the zinc industry of the province, and as a result zinc ores were being exported to foreign countries to be manufactured into spelter and zinc oxide. That meant that Canada first paid freight on the raw material taken out of the country and afterwards paid freight and duty on the manufactured zinc products it imported. It was estimated that Canada in that way paid more than two cents per pound on all spelter it used and proportionately on other zinc finished products. Heavy losses had been incurred in the large quantity of zinc, together with the silver in it, run to waste in concentrating silver lead ores, the tailing from a dozen 100-ton concentrators assaying from 20 to 30 per cent. zinc, and in the penalties paid the smelters for the excess percentage of zinc in the lead ores marketed. But the position had become much changed, for while it was developing that to a considerable extent zinc was replacing lead at depth in important mines, methods for the recovery of zinc were being steadily improved and—an important consideration—spelter commanded a higher price than did lead. Peculiar and extraordinary conditions had caused the advantages and prospects of the zinc-mining industry to be overlooked, but it was being realized that there was a promising future for zinc in British Columbia, and that it would add a new and distinct branch to the mining industry of the province.

Commission to Investigate Zinc Resources.

As a result of the representations made from British Columbia, the Dominion Government in the summer of 1905 appointed W. R. Ingalls, of New York, "to

make an investigation of the zinc resources of British Columbia and their commercial possibilities." It also designated Philip Argall, of Denver, Colo., and A. C. Garde, of Sandon, B. C., as his assistants, the former to have charge of the field work and the latter to assist him. Henry F. Wood, of Denver, was appointed to investigate the adaptability of the ores of British Columbia to magnetic and electrostatic concentration, etc., Mr. Ingalls was directed to make a tour of the zinc districts of British Columbia after the field work should be sufficiently advanced, to obtain such personal view of the economic conditions as would enable him to form a sound judgment regarding the establishment of zinc smelters, fuel supply and strategical railway locations and such other data as would be necessary for arriving at proper conclusions affecting the development of the zinc industry of British Columbia.

The report contained between 300 and 400 pages and was freely illustrated. In the introductory chapter Mr. Ingalls dealt with the history of zinc mining and smelting in the West, statistics of production, character of the ores, markets for ores, valuation of zinc ores, cost of smelting, value of argentiferous blende, and wet processes of zinc extraction. Other chapters gave much detailed information relative to the zinc mines and the undeveloped zinc resources of British Columbia, methods for concentration, assaying, etc.

Dominion Government to Conduct Experiments.

No considerable progress towards placing the zinc-mining industry on a permanent basis in British Columbia has yet been made. Much money was spent by one company operating mines in the Ainsworth and Slocan mining divisions in the erection and equipment of works designed to produce spelter, but commercially these were a failure. Other works were afterwards built and equipped, these for the treatment of complex lead-zinc ores by electro-thermic energy, but here again results were unsatisfactory and operations were not continued. Meanwhile a duty was placed on zinc ores entering the United States, so those interested in the mines in Ainsworth and Slocan districts held a meeting at Nelson, B.C., last December, and thereafter petitioned the Dominion Government to take the steps necessary to establish a smelting plant capable of treating Canadian zinc ores and of producing manufactured products of zinc, at least to the extent of supplying the Canadian market for the same. Especially it was asked that the Dominion Department of Mines be authorized to take up the matter and conduct experimental work upon such a scale as will determine definitely the practicability of the economical treatment of zinc ores by electro-thermic or electro-chemical process.

On March 21, Hon. Wm. Templeman, minister of mines for Canada, introduced in the House of Commons a resolution providing for the expenditure of $50,000 for the purpose of investigating the processes in use in the production of zinc, and for experiments in the manufacture of spelter and other zinc products from Canadian zinc ores. It is understood the experiments will be made at Nelson B.C., probably at the works in existence there and at which much experimental work has already been done.

In conclusion, it may be mentioned that last year zinc ore and concentrates containing about 11,000.000 lbs. of spelter were shipped from mines in Ainsworth and Slocan divisions. Lucky Jim mine shipped to the United States about 5000 tons or ore averaging about 52 per cent. zinc, while the Whitewater, Ruth, and Van Roi shipped concentrates running about 45 per cent. zinc. Other mines in which it is known zinc occurs in considerable quantity are the Blue Bell, on Kootenay Lake; several mines in Ainsworth camp; the Cork, Province, and Montezuma, on south fork of Kaslo Creek; the Jackson, Antoine, Rambler-Cariboo, and Washington, in McGuigan basin; the Payne, Ivanhoe, Slocan Star, and Richmond-Eureka, near Sandon; several mines near Cody; Monitor and Idaho-Memo, at Three-Forks; Mountain Chief and Bosun, near New Denver; Emily-Edith, Standard, Wakefield, Hewitt, and Galena Farm, in Silverton camp; Enterprise, on Ten-Mile Creek, Slocan Lake; and numerous smaller mines. There is a large deposit of zinc ore in the Arrow Lake division, now being opened by New York men; much zinc in the Monarch mine, near Field, on the Canadian Pacific main line railway; and known undeveloped occurrences of zinc ore in Lynn Creek camp, near Vancouver; at the Britannia mine, on Howe Sound; in the Quatsino Sound district, Vancouver Island, and in other places in the British Columbia coast district.

*Report of the Commission appointed to investigate the zinc resources of B.C. and the conditions affecting their exploitation. 1906, Mines Branch, Dept. of the Interior, Ottawa.

From the smoke pollution investigation that has been in progress for a number of years at Leeds, England, it appears that the solid impurities in the air at the industrial centre are 20 times as great as three miles to the north-east. The soot washed down by rain over four square miles in the industrial centre averages 190 tons per square mile per year, or half a ton per square mile per day, and at one station reaches the rate of 300 tons per square mile per year. The waste in unburnt fuel is represented by about 100 tons per square mile per year. The tar deposited with the soot has been estimated to be 24 times greater in town than 9 miles away, and has been shown to be 80 pounds per acre per annum in the centre and only 14 pounds three miles to the northeast, although the proportion is higher in domestic smoke than in industrial smoke. The free acids—sulphuric and sulphurous—in the air at the centre represent an annual deposit of 90 pounds per acre, or 25 or 30 tons per square mile. The solid impurities in the air often reduce daylight one-half, the tarry matter causes the soot to adhere to buildings and vegetation; the sulphurous acid makes town fog irritating when breathed and is very injurious to agriculture, and the chlorides—chiefly common salt—are sufficient in industrial centres to damage plants. The ammonia and other nitrogenous compounds in smoke, on the other hand, have some beneficial action as fertilizers and in neutralizing the acids.

For the first time on the Rand, mules have been employed for tramming operations underground. This experiment has been made in the Ferreira Deep mine, and it is stated to be successful. There has been considerable opposition in this country to the employment of animals underground, and probably there will also be a similar opposition to their employment in the Transvaal mines.

The lead smelters of the Broken Hill Proprietary Company, at Port Pirie, South Australia, have a capacity of 80,000 tons of lead per year.

Asbestos fibre brattice-cloth is being utilized in several Canadian collieries. There is much to commend it.

ERUPTIVE PRODUCTS.

The products derived from molten magmas can be classified broadly into five groups:—

(1) Normal rocks, plutonic or volcanic.

(2) Ores separated directly from molten material, e.g., nickeliferous pyrrhotite and titaniferous magnetite.

(3) Pegmatites, distinguished in origin from normal igneous rocks by the fact that water has played a more prominent part in their formation.

(4) Mineral veins and certain other mineral deposits, in which water has played a still more important part than in pegmatites.

(5) Products of gaseous or fumarole action (pneumatolitic products).

In this classification the products of eruptive action are confined to those formed beneath the surface of the earth and account is not taken of those originating at the vents of volcanoes.

It is but to be expected, since the five groups of products are so closely associated in origin that types of ore bodies would be found which represent not only each separate class of eruptive product, but various combinations of them. For instance, nickeliferous pyrrhotite and other ores are closely associated with certain rocks, ore grading into rock and vice versa. Cobalt-silver ore deposits furnish a good example of the association of several eruptive products. The diabase so characteristic of the Cobalt area, together with cobalt-silver ores and the aplite or pegmatite of the Elk Lake and Gowganda areas are all considered to have come from one magma. Fissures in the diabase, a rock which can be placed in group (1) of the classification, are occupied by the ores which belong to group (4) and by aplite or pegmatite, group (3). No pneumatolitic products are known to occur in the ore deposits of Cobalt or in the surrounding district. Fluorspar, however, occurs in similar veins of the Port Arthur silver area. Hence it can be said that in the silver areas of Ontario four groups of eruptive products are represented. In the Elk Lake and Gowganda areas ore and pegmatite are so closely associated in certain fissures in the diabase that they can be said to approach closely in origin products of group (2) Practically, therefore, all five eruptive products are represented in Ontario's silver deposits.

W. G. M.

In spite of the gradual reduction of coal consumed per horse-power per hour from more than 10 pounds to 3-4 pound, the total consumption of fuel is increasing in every civilized country. Cheapening of power costs widens its commercial applications.

Under the superintendence of Mr. F. Hille, the Laurentian gold mine is to be operated once again. A new company, composed largely of Detroit investors, has secured control of the property. The corporate name is Merger Mines, Limited.

LEGAL COLUMN.

An Official Guardian for Companies.

Reference was made in this column some time ago to the sale of shares at a discount, and it was there pointed out that the sale of shares at a discount rendered wholly uncertain the value that the purchaser was getting for his money. The elimination of the right to sell shares at a discount would leave only one loophole for the promoter to escape giving the investor value for his money, namely, the right to exchange properties or considerations other than money for fully paid-up shares in the company. This is a right that exists not only in our own systems of company law, but also in the English and American systems. It was President Taft's proposal some weeks ago to cause all properties taken over by companies to be taken over at a value set by Government appraisers which aroused such alarm on the Stock Exchange. I gathered from the weekly market letters that the foundations of commerce were threatened by the proposal.

This idea, however, is not distinctly new or strange. It has been suggested by authorities not generally regarded as anarchistic. In fact it was only after a series of cases in the English courts that the right was established at all, and the judges there have not always been enthusiastic about its merits.

Lord Justice Vaughan Williams, of the English Court of Appeal, in the case of Moseley vs. Koffy-Fontein Mines, Limited, in 1904, said:

"It was established long ago that the obligation of a "shareholder to pay the full nominal value of his "shares need not be satisfied in money's worth. It has "also been held that the Court will not, if it is satisfied "that there is an honest bargain under which the "money's worth is paid, inquire into the adequacy of "the consideration. These two propositions have been "apprised by the higher tribunal and I am not suggesting for a moment that the cases which established "them were not properly decided, having regard to the "terms of the Companies' Act, 1854, but I hope that "the day may come when it will be gravely considered "by the Legislature whether it is not for the advantage "of the community and particularly of the commercial "community, that an Act should be passed that in all "cases the full nominal value of the shares shall be "paid in cash and nothing else. I am satisfied from "my own judgment and experience in the administration of companies that such a law would have a tendency to benefit the companies themselves and also to "check a great deal of unwholesome speculation on the "Stock Exchange, which is largely fed and supported "by operations undertaken by vendors, promoters and "others for the purpose of unloading fully paid shares "which they have been allowed to satisfy by giving "what is called 'money's worth' instead of making a "cash payment."

Perhaps it should be explained that this is the source of all bonus stocks, stocks issued at a discount (other than mining stocks), and all the other manifestations of watering.

This is a very difficult matter to attack. Unless the practice of issuing shares of mining companies at a discount—a malpractice without either legal or moral justification—these decisions are based on a sound principle of contract law, that people must be at liberty to

make their own bargains, and if they are fools, must pay for their folly, or, as Lord Eldon said, mere inadequacy of consideration, unless it be "so gross as to shock the conscience and amount in itself to conclusive evidence of fraud," is not sufficient to annul a contract.

Now a company is in the eyes of the law a person, able to contract and act within its powers as well as a living person. Being able to contract, it is presumed to be able to protect itself. And so the same principle is applied to the sale of stock for money's worth. Lord Justice Cotton: "The Court will decline to rip up a transaction not impeached as dishonest and not proved to be such, merely because the company may have paid an extravagant price for their property." Vaughan-Williams: "The Court ought to go into the question of whether there is real consideration or whether the consideration is a sham—but in my judgment you can only impeach it in cases where the evidence justifies you in saying that the transaction is a colourable one." Lord Lindley in the same case on appeal:" Shares in limited companies cannot be issued at a discount. By our law payment by a debtor to his creditor of a less sum than is due does not discharge the debt; and this technical doctrine has also been evoked in aid of the law which prevents the shares of a limited company from being issued at a discount. It has, however, never yet been decided that a limited company cannot buy property or pay for services at any price it thinks proper and pay for them in fully paid-up shares. Provided a limited company does so honestly and not colourably, and provided that it has not been so imposed upon as to be entitled to be released from its bargain, it appears to be settled that agreements by limited companies to pay for property or services in paid-up shares are valid and binding on the company's other creditors."

That is to say, the ordinary principles of contract law only are to be applied to such sales of stock. But there are other principles of contract law which should be considered.

A company is presumed to be a person, but is a person entirely under the influence of its directors, and they, in such cases as we are considering, are usually the promoters or the vendors. Thus the company is a person that cannot think or act but as the promoters or vendors will. A contract made with a real person under these circumstances would be absolutely unenforceable and could always be set aside. The person contracting must be as regards the other party "placed in such a position as will enable him to form an entirely free and unfettered judgment independent altogether of any sort of control."

The question is settled, however, as far as the courts are concerned without any regard to any argument about "undue influence." What should the legislature do about it? To require all stock to be paid for in cash hardly seems possible. It is hard to conceive of a workable law to that effect that could not be evaded. To require appraisers to value all the various assets that are turned over, appointing as it were an official guardian to companies, seems to suggest complications and delays that the future hardly promises leisure for. Yet there is a considerable parallel between companies theoretically capable but actually incapable of independent acts, and infants whose bargains the court and the official guardian supervise.

It is not so fantastic an idea. The company is a person with full powers up to a certain limit. Beyond that it is not existent—why not create a borderland of infancy where it can act if the court and its guardian approve? In this borderland we might place the sale of stock for money's worth, the issue of prospectuses, mergers and other dangerous acts that will suggest themselves. More than the mechanical supervision of the government is needed. The machinery is at hand. Why not try using it?

BOOK REVIEWS.

REVIEW OF THE COPPER HANDBOOK, VOL. IX.

The ninth annual edition of the Copper Handbook, edited and published by Horace J. Stevens, Houghton, Michigan, is just to hand. This work, which has become a standard authority on the subject, has, in its latest edition, 1,628 octavo pages, containing considerably more than a million words, and, in addition to the miscellaneous chapters, lists and describes no less than 7,751 copper mines and copper mining companies, in all parts of the world, descriptions ranging from two or three lines in the case of companies that have died recently, to sixteen pages in the case of one of the largest mines—a mine, by the way, that employs some seven thousand men and has paid dividends of considerably more than a hundred million dollars. The mine descriptions are the same as in the preceding volume, except that upwards of eight hundred new titles have been added, covering descriptions not contained in any previous edition. The chapter of statistics, containing upwards of forty tables, treating of copper from almost every conceivable standpoint, has been fully revised and brought as nearly as possible to date.

The miscellaneous chapters of the book, twenty-four in number, treat of the subject of copper from a great variety of viewpoints, including the history, chemistry, mineralogy, metallurgy and uses of the metal, and this section of the book also has chapters devoted to substitutes, alloys, brands and grades, and a copious glossary.

The plan on which the book is sold has remained the same for seven years past, the publisher sending the book by mail, fully prepaid, to any address ordered, without advance payment of any sort, and subject to approval after a week's inspection. The price is $5.00. That this unusually liberal plan has proven successful is shown by the statement of the publisher that net losses through returned copies and defaulted payments are less than four per cent. Anyone interested in the subject of copper, as producer, consumer, or investor, should order a copy of the Copper Handbook.

PERSONAL AND GENERAL.

Mr. P. N. Nissen has settled temporarily in Toronto.

Mr. C. S. Herzig, of the Constant-Herzig Company, is examining a mining property in West Virginia.

Mr. H. Mortimer-Lamb is to represent the Canadian Mining Institute at the International Mining Congress in Germany.

The Constant-Herzig Company is about to undertake examinations of properties in Utah and Nevada on behalf of London clients.

Mr. James Bartlett has resigned his position on the staff of the Ontario Bureau of Mines and has accepted a billet with the Hosmer Coal Company, Hosmer, B.C.

Mr. A. J. Beaudette, formerly mining engineer for the Dominion Government in the Yukon, has recently visited Sudbury, Cobalt, and Porcupine. Mr. Beaudette will, during the coming summer, make professional examinations in many parts of Canada. It is probable that he will then make Vancouver his headquarters.

Mr. Alexander H. Smith, engineer for A. E. Osler & Company, and other interests in Porcupine, is in Toronto.

Mr. R. B. Lamb, of the C. L. Constant Company, has returned from a professional visit to Nicaragua.

Mr. T. J. Brown, the general superintendent of the Nova Scotia Steel & Coal Company, recently underwent an operation for appendicitis. He is understood to be making good progress towards recovery.

The following paragraph has gone the round of the newspapers:

IN HANDS OF RECEIVERS.

New York, March 28.—The Canadian Consolidated Mining Company, Limited, at 103 Park Avenue, with an authorized capital stock of $5,000,000, a holding company for several coal mining companies in New Brunswick and Nova Scotia, was put into the hands of receivers to-day, as it was unable to raise money to pay its obligations. Judge Greenbaum, of the Superior Court, appointed Daniel P. Hays and David Davis, receivers, with a bond of $75,000, on application of Julius O. Foote, attorney for Luella N. Von Hagen, who is creditor for $19,500 on a note of the company and owns $1,100,000 of the stock.

Hugo Van Hagen was president of the company. The liabilities are $50,000. The company was incorporated under Maine laws in March, 1909, with a capital stock of $5,000,000, of which $4,840,000 has been issued. It owns stock in the following companies: North Shore Railroad Company, Northern Coal Company, Kent Coal Company of New Brunswick; Kent Coal Company, Maine; Crown Coal Company and Great Northern Coal Company, of Nova Scotia, and Maritime Coal Company, of New Brunswick.

The Montreal Star speaks of this as "Another Mine Bubble Burst." It is hardly correct, however, to speak of Von Hagen's companies as "bubbles," because they were frauds pure and simple. We do not remember to have seen any references of late in "Financial Facts" to the dividends of these companies, and Mr. Henry Roach has been strangely quiet of late on the remarkable possibilities of "Kent Coal." It comes to our recollection that this gentleman in advertising the Great Northern Coal Company of Nova Scotia said that future generations would bless the day they heard of Mr. Henry Roach and the wonderful wealth which reposed in the areas of the Great Northern Coal Company, all unknown to the unsophisticated inhabitants of Maccan. It is more than probable that the trusting servant girls and widows who handed their savings to the unspeakable Roach are to-day doing anything but bless that well-named gentleman. The true history of the Canadian Consolidated Mines Company, Limited, would enrich the Newgate Chronicle, and the makers of that history should be allowed to take their ease in Sing Sing or some other classic residence for gentlemen who defraud and embezzle.

According to Mr. David H. Browne, metallurgist of the Canadian Copper Company, it has heretofore been found impossible to produce by melting copper and nickel together an alloy having the same physical properties as the alloy produced direct from the matte.

Mr. David H. Browne, in a paper read before the A. I. M. E., at the recent Pittsburg meeting, states that experiments on the conversion of copper-nickel mattes led to the following conclusions:—

1. Nickel is not an element replacing iron in matte.
2. Nickel-copper alloys act in the matte-blow like one metal.
3. Nickel-copper alloys follow, during the matte-blow, exactly the same laws as govern the behaviour of copper alone.

In 1908, 140 by-product coking ovens were erected in the United States. The number of completed ovens at the end of the year was 4,007. The net gain over the previous year was, however, only 115, as 25 Semet-Solvay ovens at Sharon, Pa., were dismantled.

The daily production of coal in the Nicola Valley country, B.C., has increased during the past winter. Coal cutting machines are being used successfully.

At the Testing Station of the U. S. Geological Survey, Technological Branch, at Pittsburg, all "permissible" explosives are put through three series of tests. In one, a mixture of gas and air containing 8 per cent. of methane and ethane is used; in another, a mixture of gas, air, and dust, containing 4 per cent. of methane and ethane, is used; and in another, dust and air without gas are used.

Crude oil has been adopted as a preservative by two large American railways. Railway ties treated three years ago, when taken out and examined were entirely free from decay.

Fifty-seven per cent. of the total producer gas horsepower in the United States is developed from bituminous coal and lignite. Two producer gas plants that will utilize peat are in course of construction.

Josephinite, a natural nickel-iron alloy found in placer gravels, contains, according to one analysis, 60.45 per cent. nickel, 23.22 per cent. iron, 0.55 per cent. cobalt, and 12.26 per cent. anhydrous silicates.

EXCHANGES.

The Engineering and Mining Journal, April 16th, 910.—In the Coeur d'Alene district, according to Edward S. Wiard in the latest of his excellent articles on "Ore Dressing in the Coeur d'Alene District," the vanner is the final concentrating machine. Its chief advantage is that a high-grade concentrate can be made and this is attained largely by the shake of the machine. The shaking causes high tailings. To secure low tailings and clean concentrates, Mr. Wiard argues that the vanner should be used in the first treatment of material too fine for successful separation on tables of the Rittinger type. The tailings can then be led to convex revolving buddles, the low-grade made on the buddles being enriched on a vanner and the tailings from the latter returned to the buddle. For retreatment work of this kind, Mr. Wiard regards the buddle more favourably than the vanner. Vanners, he states, might be run better than in most mills.

The Mining World, April 16th, 1910.—The Mining World, referring editorially to the care of machinery, alludes to the necessity of having on hand at the mine duplicate parts of machines that are especially liable to become broken or worn out. Regular inspection should never be omitted. Machinery can thus be kept in proper adjustment and properly lubricated, and weaknesses detected before a breakdown may occur.

The Daily Mining Record, Denver, April 16th, 1910.—The Record has this to say concerning drill-hole ore reserves:—

"A critical attitude toward the drilling operations at the so-called porphyry copper mines of the West has recently developed among followers of the mining share markets. The disposition to scrutinize ore reserves very closely is usually the result of a series of market disasters, and this appears to explain the discussion concerning the permanency and value of the deposits that are calculated from drill hole data. A mistaken conclusion regarding this type of mines has in some quarters been drawn from the recent unfavourable reports concerning the Granby of British Columbia, which does not belong to the same class as Utah Copper, Nevada Consolidated and others like them, and is being operated upon a different system of ore treatment. Nevertheless, the Granby incident has evidently served to bring under review the whole question of ore reserves in the low-grade copper mines and to reflect unnecessary doubts upon the permanency of the so-called porphyries.

"It is certainly true that drill holes 200 feet apart cannot supply data concerning the mineralized character of the ground between them, and that the actual proof of the ore must follow from the usual developments, which precede production, but the inferences from experience are such as to satisfy some of the best mining men in the business. Blocked out ore is not predicated upon the data of drill cores by anyone, and it is just as well that the investor in stocks should fully understand this. The results of drilling can mean that large mineralized areas are present, but they mean also that regular development is necessary before any production can be made. In some quarters it is contended that the ores usually prove to be higher in copper tenor than the drill cores show, but it may require more experience to fully establish this as a rule.

"The ores indicated by drills may be called conditional reserves, but the condition has not yet been shown to be material. Some engineers think such results are ample, and are willing to accept them as close approximations, while others are not willing to accept the figures thus secured and expect verification by the usual standards of development before offering any calculations at all.

"In our judgment it is merely the argument of a stock market 'bear' that seeks to undermine the element of assurance as to the life of 'porphyry' deposits indicated by the drill holes, when these have been put down in great numbers over large areas. It is normally sufficient to urge that exact tonnages and exact values cannot be determined save by development. It may serve the 'bear' to remember that even the best sampling of a mine can give only an approximation. Safe approximations are all that the mine explorer is after, on the hither side of smelter returns."

CANADIAN PATENTS.

The following is a list of Canadian patents granted on April 12th, 1910, relating to mining and metallurgy and furnished by Fetherstonhaugh & Company, 5 Elgin street, Ottawa, Canada, Russel S. Smart, resident, from whom all information regarding same may be obtained:

124928.—A. S. Ramage, Newark, N. J., Methods of recovering iron from ores and preparing iron alloys. The Electrical Steel Company of Canada.

124968.—Wm. H. Fletcher, Jackson's Drift, Transvaal. Mills or apparatus for crushing or pulverizing ores, minerals and the like.

124980.—A. H. Kidney, New York, N. Y. Means of exhausting and condensing furnace fumes.

124993.—Chas. M. Mullen, Portland, Ill. Car roofs.

124989.—F. D. Melhuish, Atlanta, Ga. Ore concentrators.

124990.—C. Miele, Gutersloh, Westfalia, Germany. Processes of producing a uniform metallic coating.

124991.—Jas. E. Moody, Toronto, Ont. Centering molds.

125008.—A. Poulson, Farnworth, near Wednes, County of Lancaster, Eng. Manufacture of gelatinous silica.

125011.—A. S. Ramage, Buffalo, N. Y. Processes of producing electrolytic copper.

125012.—A. S. Ramage, Buffalo, N. Y. Processes for the separation of mineral combinations.

125013.—A. S. Ramage, Buffalo, N. Y. Processes of recovering metals from ores.

New Brunswick gypsum compares very favourably in point of purity with gypsum from other countries. Hillsboro', N. B., gypsum contains 79.55 per cent. calcium sulphate, 20.94 per cent. water of combination, and not more than 0.10 per cent. of any one impurity.

Meteoric iron, according to analyses by chemists of the United States Geological Survey, ranges from 4.81 per cent. to 14.95 per cent. nickel.

The Commonwealth Oil Corporation, an English concern formed to exploit the oil-shales of New South Wales, will depend largely upon government protection in marketing its products.

CORRESPONDENCE.

To the Editor Elk Lake, April 21st, 1910.

The Canadian Mining Journal, Toronto.

Sir, — I should like through the medium of your paper, to draw the attention of those interested in mining matters throughout Ontario to the law pertaining to the survey of claims as laid down in The Mining Act of Ontario, sections 113-116.

In section 113, clauses 2, 3, 4 and 5, the method of surveying claims is laid down for the benefit of the surveyor, but this method doesn't do the prospector or owner of a claim much good.

If the surveyor ties up his posts, and runs a tie line to the nearest known point, his duties are apparently ended.

But it often happens that claims overlap, and two or even three parties may imagine that they own the same ground.

The survey then is of no use, except to outline the ground in dispute, and the result is generally an expensive lawsuit, a luxury which very few prospectors can afford.

I quote the following case, (similar to many others), which was brought to my notice yesterday by a disgusted prospector.

He, or his partners, staked a fraction near Leroy Lake, Gow Ganda district, which fraction is surrounded by claims since proved to be very valuable.

To make sure of doing his work within his boundaries, he had his fraction surveyed, did his thirty days' work, and got a certificate of record.

This was last year. Twice the property was nearly sold. The "Abstract" showed it to be in "good standing."

Lately, however, he returned to Leroy Lake to do his second year's work and was astonished to find that someone else had done some considerable trenching on his ground.

Not understanding the reason for this, he took a trip to the Recording Office at Gow Ganda, and found that another party held a certificate of record covering the same ground, and that a third party also had done work on, and claimed the property.

How can a law which permits such a mix-up to be possible, benefit the prospector.

My friend is out the price of the survey and thirty days' work, and was told candidly enough by the recorder at Gow Ganda, that the best thing he could do was to let the claim go, as he hadn't a leg to stand on if he tried to fight the case!

And supposing he had done his second year's work last autumn, instead of leaving it till the spring, he'd have been out that much too, and apparently he has no redress.

I should like to see the survey of claims carried out throughout Ontario on similar lines to the survey in British Columbia.

Before starting out to survey a claim or group, let the surveyor, having access to the recorder's office and working in conjunction with him, examine the books showing applications of record for surrounding claims.

Then let him CUT OUT those portions of claims overlapping the claim he is surveying and which have prior rights to that claim.

The claim then as surveyed, or what is left of it, will beyond doubt be the ground to which the locator is entitled.

This doesn't mean much more work for the surveyor, but it means a great deal more satisfaction for the prospector.

And after all who is entitled to the protection of his interests more than the prospector, who for the most part spends what he gets in developing the country.

One more point I should like to bring forward.

The survey of a mining claim in British Columbia is equivalent to an assessment, and is recorded as such—the assessment being valued at $100.

The advantage to prospectors and would-be prospectors, of having claims surveyed is obvious—the boundaries are absolutely defined, and its location.

Why not, then, let it take the place of thirty days' assessment work out of the 240 days which has to be done before a patent or lease can be granted.

After all, does thirty days' work more than counterbalance the benefit gained by definitely outlining a locator's claim?

As things stand at present too much money is spent by prospectors and claim owners in lawsuits, which are prejudicial to a mining community.

The government would lose nothing by the change and the prospector would benefit much.

Yours truly, R. O. Hawtrey.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay, April 14th, 1910.—The weather conditions in the Gulf of the St. Lawrence have been most favourable to an early opening of navigation, and the collieries have taken advantage of the absence of drift-ice and the open state of the river to make early shipments of coal to Montreal. The first steamer to arrive from sea at Montreal was the Kron Prinz Olaf, which reached Montreal on the 12th of April. The earliest recorded arrival from sea at Montreal previously was the 22nd of April, so that this year's performance will doubtless establish a new record that will stand for a long time. Both Sydney and Louisburg have been completely free from drift-ice this spring.

The annual meeting of the shareholders of the Dominion Coal Company was a notable one in many respects. In commenting on the decreased earnings of the Coal Company many of the newspapers stated that the United Mine Workers' strike had caused an expenditure of $1,250,000, which is an entirely incorrect view of the matter. In comparing 1909 with the years immediately preceding it, it must be remembered that the Coal Company's earnings included the excess price paid by the Steel Company for its coal during the contract litigation. It must also be noted that the first part of 1909 was a period of depression in the coal trade. In view of these two facts and the strike it is distinctly encouraging to coal shareholders to know that their property was able to earn $1,100,000 on an output of 2,734,000 tons, which is just about one million tons less than the output capacity of the mines. That such a result should have been obtained says a good deal for the manner in which the officers of the company fulfilled their duties in the face of great difficulties. One of the company's mines was idle practically the whole year, and another mine had not fully recovered from the effects of a disastrous fire.

The company has been compelled to police practically a whole county, and it seems not a little anomalous that a Canadian corporation in which a large amount of Canadian capital is invested, should have been allowed to be harassed by the

alien delegates of a foreign organization. The situation partakes of absurdity when it is also considered that a bill was actually presented to the Commons of Nova Scotia proposing that recognition of this union should be made compulsory on the coal companies. In view of what has passed, a legislature that should dare to enact such a law should be impeached for treason. The courts of Nova Scotia were also used by this alien union to further harass the coal companies with the aid of funds from the United States. This American union has no respect for our courts of justice. The restraining injunction of Judge Lawrence has so far been treated with absolute contempt, and not only have the foreign officers of the U. M. W. refused to obey the injunction of the Nova Scotia Supreme Court, but they have openly advised their followers to pay no attention to it. The argument of the international unions is that Labour should not be refused the right to international affiliation and combination, while Capital is under no such restrictions. This argument cannot wholly be gainsaid, but the fallacy lies in the fact that combinations of capital are made under the law of the land for a lawful and usually beneficial end, whereas the actions which have been pursued by the United Mine Workers in the strike at Glace Bay, have been unlawful, and the persons who have been sent here from the United States to direct the operations of the U. M. W. are not amenable to the laws of this country—laugh at them in fact. There has been a virtual state of war in Cape Breton for the past nine months, but the enemy that has attacked our home industry has been under the protection of Canadian laws, and no contraband has been declared against his munitions of warfare. As the Canadian law stands to-day, no industry in this country is safe should the head of a United States labour organization decide to concentrate the resources of that organization against one particular company. Surely our industries are entitled to some protection against the foreigner. It is true that no part of the Empire has as a neighbour so populous and wealthy a nation as the United States, but considering even this fact it is almost unthinkable that such a state of affairs as exists at Glace Bay to-day could be permitted in any other part of the British realm. It has been said,—and who can contradict it?—that the unrest which the U. M. W. have caused in Nova Scotia is viewed with favour by coal operators in the United States, because it serves their ends and their designs upon the Canadian coal market. If this were so the laws of Canada afford no remedy, and the Canadian shareholder must bear the brunt. Persons travelling by the Sydney & Louisburg Railway may any evening see workmen living along the line side escorted to their homes by policemen, and will notice that the houses of the men who dare to work, despite the mandate of a gentleman in Indianapolis, U.S.A., are all shuttered with heavy boards to prevent stones and other missiles from being thrown through the windows at the occupants. This is one example among hundreds of the state of affairs which has been allowed to continue at Glace Bay and around the collieries. Until the arrival of this American organization, with its medieval methods, the colliery districts had been remarkably orderly, considering the mixture of nationalities and the quality of the whiskey which is dispensed in the saloons of Glace Bay. The town of Glace Bay had a very limited number of policemen, and one solitary constable constituted the protection which the Coal Company considered necessary for the property and the persons of its workmen. The collieries were all unfenced and completely open to the public. To-day every colliery is enclosed by a fence, which is illuminated at night. The company has to maintain a large force of uniformed constables, and hitherto innocent citizens go about "heeled" like a Western desperado. The change is a remarkable one, but it is also one which has marked the advent of the United Mine Workers in other places. This unfortunate state of affairs could not have come about had not the leaders of the U. M. W. worked their astute and ancient game of setting the political parties of this province by the ears—not that this is a difficult matter—but surely it is by this time apparent to both Liberal and Conservative that the unfortunate miners who have followed the lead of the U. M. W. are being heartlessly exploited by this organization, and that eventually, unless this pernicious nest of disturbers is driven from our province, these deluded men will lose all they have and be driven either to leave the country or become paupers on a county already saddled with extraordinary expenses also due to the presence of the U. M. W. in Cape Breton. Many of the strikers are men enthused with the martyr spirit, confident that they are fighting the battle of right, and they are content to be herded together, as one of themselves worded it "like rats in a hole," while their leaders eat dollar dinners on the Intercolonial Railway, and attend conventions in the Land of the Stars and Stripes. The officer who shares the hardships of his men gains their respect and confidence, but the "walking delegate" from Indianapolis, Kansas and Alabama, as we know him in Glace Bay, is a parasite, and sooner or later must meet with the fate that befalls all such creatures when their victims realise their presence.

ONTARIO.

Cobalt.—The agreement between the Chambers-Ferland Mining Company, and the Ontario Government regarding the royalty reduction has at last been signed. The Chambers-Ferland has done practically no shipping for a year, waiting, it is said, in the hopes of getting the royalty reduced, and now that it is a settled fact they will join the list of regular shippers. It is understood that there is a considerable quantity of both high and low grade ore on hand. When this is shipped it will, of course, come under the reduced royalty. Formerly this company paid 25 per cent. of the gross proceeds of the ore, but now they only pay 25 per cent. of the net proceeds. At present there are three high grade veins being worked and the second class ore which runs in the neighbourhood of 250 ounces, is an important consideration. Several promising veins have been discovered on the Nipissing property near the Chambers-Ferland and this section will be thoroughly prospected this summer.

Another ore shoot has been opened up on Peterson Lake lease of the Little Nipissing. From the bottom of the winze, which is down 240 feet, a cross-cut was run and when in about 20 feet the vein was cut. It shows from two to three inches of smaltite carrying native silver. This property is now getting air from the Mines Power and it is the intention of the management to operate four drills. The property was formerly greatly hampered on account of the lack of power.

The shipments for the month of March were quite heavy and show an advance of about 420 tons over the previous month, and are about 100 tons greater than the shipments for the corresponding month of last year. Altogether eighteen mines sent out 84 cars aggregating 2,601 tons Three new shippers have been added to the list, the Waldman, the Hagraves and the Chambers-Ferland. With the exception of the Provincial Mine, the Waldman is the first property to ship ore from the Gillies Limit. The McKinley-Darragh shipped more high grade ore during the month than any other property, and with its increased mill capacity it is expected that it will be able to maintain a large output.

The Hargraves has cut the No. 1 vein at the 125-foot level in a cross-cut from the shaft. Where cut the vein was about four inches wide and carries high values in silver. This vein was found near the Drummond boundary on the surface and at the 75 foot level good ore was found in the conglomerate. The shaft was then continued and the vein picked up on the lower level. At the lowest level of the No. 3 shaft a winze is being sunk on the vein and will be continued for about 60 feet.

Since the Bailey obtained power to run its hoist and com-

pressor, underground work is proceeding much more rapidly and good results have already been obtained. A winze has been put down twenty-five feet below the tunnel level, and has disclosed a considerable body of medium grade ore. There is about four feet that will assay nearly five hundred ounces. The main values, of course, are carried by several stringers of high grade ore, but the rock lying between these is also well mineralized. The main shaft is to be sunk an additional fifty feet, and from the bottom a cross-cut will be run to open up the Bailey vein, which is the principal ore body so far discovered on the property. The plant consists of the first half of an electrically driven twelve drill compressor and an electric hoist. The compressor will in all probability be shortly discarded for the Power air. Arrangements have been made with the Cobalt Central to treat 500 tons of the Bailey ore in the former company's mill.

Judgment has been rendered in the action brought by the Peterson Lake Mining Company against the Nova Scotia, with regard to the latter company's lease on Peterson Lake. The Peterson Lake had an injunction issued restraining the Nova Scotia from mining the lands covered by the lease. This has been dissolved. The Peterson Lake also claimed the lease to be forfeited on account of non-compliance with its conditions. The judge stated that he was unable to find any evidence pointing to fraud and that although there might have been failure in some cases to comply with the literal terms of the lease, such failure was acquiesced in by the representatives of the plaintiffs. The royalty has been fixed at 25 per cent. of the gross value of the products and not 25 per cent. of the net proceeds, as claimed by the Nova Scotia.

At least three promising properties in South Lorrain have changed hands during the past two weeks, and negotiations are under way for several others. The Mitchell-Brocklebank claim in the vicinity of Ox Bow Lake has been sold for $25,000. Practically no work has been done on this property, but several promising veins, some carrying smaltite, have been uncovered on the surface. The Martin claim, in the same locality, has also been sold to New York and Philadelphia people for a good figure. This property has not been developed, but a company is being formed to take it over and work it this summer. New York people also purchased the claim known as H. R. 227 for the sum of $15,000. The district of South Lorrain is growing in importance every day and should become one of the most important camps outside of Cobalt. The installation of the substation by the Mines Power Company for the distribution of electric power, will have a very beneficial effect. This power is to be sold at $50 a horse-power year and will mean a tremendous decrease in power costs. The Maidens property has another good ore shoot in their vein. In sinking the vein practically pinched out for a short distance, but on going down a little further the ore came in again, carrying as high values as formerly. The Haileybury Frontier has been getting good ore in the drift, and assays of over 3,000 ounces have been obtained. The shaft will be sunk as rapidly as possible and arrangements have been made with the Keeley to supply air for one drill for this purpose.

A new concern, to be known as the Dominion Reduction Company, is being formed for the purpose of building a customs concentrator to mill the low grade Cobalt ores. It is expected that it will be erected in the vicinity of Giroux Lake, in close proximity to the T. & N. O. Railway's branch line to Kerr Lake. The promoters expect to build a mill of from 50 to 60 tons capacity, and state they will have it running within four months of the date work is started on it. At the present time there are two customs concentrators in camp, the Northern Customs and the Nipissing Reduction. These mills have all that they can handle for some time to come, so that there should be a good opening for another one.

The Temiskaming mill is now running steadily and is putting through about eighty tons a day, and the shipments from this property, which have been small for the last several months, will show a material increase. The main mill is several hundred feet distant from the crushing plant and the two are connected by an aerial tramway. Considerable high grade ore is now coming from the 350-foot level, and in the process of winning it large quantities of low grade ore are also being produced. The main tonnage for the mill is, however, coming from the dump.

Another high grade vein has been found on the Wyandoh property in the Gillies Limit. It is, however, very narrow, being only about half an inch wide, but carries a good deal of native silver. Work is to be started shortly on several of the Limit lots, but so far this section of the camp has been very disappointing. It is probable that the Government will have other sales this summer, but the project will not meet with any great favour from investors in this section of the country.

The Hudson Bay has struck a high grade ore shoot in the No. 5 vein on the first level. The ore is about two inches in width and runs over four thousand ounces in silver. A small shipment from the dump was made to the Cobalt Central mill to get an idea of its average value. The results obtained were satisfactory.

Since power has been turned on at the Peterson Lake leases there has been a great increase in activity in that part of the camp. The Kerry Mining Company has opened up an ore shoot on the 200-foot level. A cross-cut will also be run from the Kerry shaft to the Scott lease. The Peterson Lake is opening up the vein from which it got its last car of high grade, and will probably have another car before long.

The long-drawn-out suit between the Coniagas Mine and the town of Cobalt has at last been settled. The case was finished some time ago, but judgment was only given within the last few days. The suit arose out of the fact that the Coniagas contended that it had the right to mine on any of the lots or streets under which it had the mineral rights. As part of its mining lands take in one of the principal sections of the town, this was a very serious matter and suit was accordingly brought. The trouble was started by the arrest of some of the company's officers for having a prospecting trench dug upon one of the streets. The mine's contention was upheld by the courts, and it is at liberty to use the surface for any mining operations it sees fit. As regards the streets, the company will have to submit a plan of proposed operations that will have the approval of the town engineer before the work can be started.

PORCUPINE AND OUTLYING DISTRICTS.

Eleven more of the claims staked by Wilson and Edwards in Porcupine, have, it is stated, been sold to the Dome Mining Company and McCormick Bros., of New York. The price is believed to be in the neighbourhood of $1,200,000. The Dome Company purchased six of the Wilson claims some time ago, among them the famous claim which was responsible for the rush into that district. McCormick Bros. were negotiating for this property but they failed to come to any agreement. On the eleven other claims just purchased the initial payment of $35,000 has been made, and the balance is payable in installments. The car shipped from the Timmins property to the States is still held up at the border, awaiting the customs clearance papers. It will be sent on to its destination in the course of a day or two. The Scottish Ontario Gold Company is at present installing its machinery, and as soon as this is in working order its force of men will be considerably augmented. The values in the bottom of the shaft are stated to be very good. The Canadian Northern Silver Mines are negotiating for the four Dixon claims. The price asked is in the neighbourhood of $50,000. A new company, known as the Porcupine Gold Mines Company, has been formed with a capitalization of $2,000,000, to work several properties known as the Vipond claims. Camps have been erected and a force of men will be employed this summer in thoroughly prospecting the company's holdings.

A short time ago Northern Ontario was startled with the report of a new gold discovery south of Matheson, and for a time the greatest excitement prevailed. Two prospectors arrived in Haileybury with samples of telluride ores which they claimed to have taken from claims they had staked near Caribou Lake, about twelve miles west of Bourke's siding on the T. & N. O. Railway. These samples were shown to several prominent men in the town and the prospectors are stated to have raised a considerable sum of money upon swearing to an affidavit that the samples came from their claims and promising to lead these men into the place. Engineers were engaged to go in and look over the ground, but before they were ready to start the news leaked out and prospectors began swarming in from all directions. In order to be first on the ground the engineers hired a special train to take them to Bourke's siding. The country proved to be practically impassable, consisting mainly of swamp and muskeg. When they arrived at their destination they found that they had been tricked and that the only sign of mineral was a quartz vein worked by one of the old settlers, on which a twenty-foot shaft had been sunk. The best assay ever obtained from it was ten dollars in gold and there were no signs of tellurides. Other prospectors going in fared badly, and one party is known to have spent three days in getting twelve miles. Blackburn and his partner are supposed to have brought their samples from the West. As soon as the engineers arrived at the railroad they telegraphed orders to have Blackburn arrested, but neither he nor Jones have been seen since It is believed that there were fully 250 men starting in to the scene of the reported discovery within two days of the time the news leaked out, and they are all swearing vengeance against the men who misled them.

The change in the mining laws of Quebec has resulted in an influx of prospectors, with the result that several promising discoveries of silver and copper have already been reported. One or two small plants are now working in the vicinity of Fabre township, and if good results are obtained a great deal of activity may be expected in this section.

Navigation has opened on the Montreal River and boats are now running between Latchford and Elk Lake. For the present there will only be one boat a day leaving each end, but a little later the Navigation Company will run two trips daily.

BRITISH COLUMBIA.

Rossland.—It is noted that the Dominion Government is taking under consideration the question of coining a one-dollar piece to take the place of the filthy one-dollar bills now in circulation. This is a laudable move. It is hoped, however, that the large silver dollars, as used by many foreign countries, will not be decided upon, as when all is said and done they are rather heavy. A coin of some more valuable metal than the ordinary silver coin could be made of a size midway between the twenty-five and fifty-cent piece that would fill the bill admirably. Something of this character would be a great advance over the heavy silver dollar and the germ-laden one-dollar bill now in daily use in the Dominion. It is estimated that from 4,000,000 to 90,000,000 germs of smallpox, typhoid, tuberculosis, diphtheria, etc., may be found on the dirty dollar bills in circulation. Surely this would warrant a clean coin being put out and the retirement of most of the one-dollar bills.

It is a pleasure to note that committees are being appointed by the Government to make a general modification of the mining laws of Canada. This will do away with the present confusing state of affairs in that direction. It is to be hoped that the committee in charge of this work will extend its labours to the question of boiler inspection, and will straighten out the existing anomalies in the various and sundry Acts on this question, which appear to be working a hardship on both mining and mill men and the manufacturers, as to some extent personalities enter into the subject, often to the detriment of those most concerned. No doubt this phase of the situation is to be considered by the committees.

The outlook at the Le Roi Mine here remains the same as for some weeks past. Mr. A. J. McMillan, in a recent interview sized the thing up in the following words: "We are diamond drilling from the 1650-foot level and have already put a number of holes down to a depth of 2,200 feet. Our plans call for a systematic exploration of our ground in this manner and we are hopeful of being just as successful in locating pay shoots as our neighbours, the War Eagle, have been."

Nelson.—The zinc miners of East Kootenay seem to think that a portion of the money appropriated for experimental work should be expended in their district. This would be all right if the work could be done economically and something would be gained. It is considered here that the experiments can be carried out locally in a very economical manner and if the results are favourable, of course, it will redound to the good of all of the zinc property in this country. There is already an experimental zinc smelter in Nelson; power from Bonnington Falls for electrical smelting can be obtained at reasonable rates and many of the important zinc mines are contiguous to this city, all of which would aid toward an economical expenditure of the money appropriated.

The Blue Bell, zinc mine, has closed down, and will no doubt remain inactive pending results of some of the experimental work on the zinc question. The Blue Bell concentrator has been treating about 900 tons of low-grade ore per week and has shipped approximately 1,100 tons of concentrate since the first of the year. Most of this ore came from the adit level, however, and while there are large deposits of this ore below these workings the mine is not properly equipped to handle it economically, so that an addition to the plant is contemplated.

The season's outlook for the surrounding districts augurs well and good strikes of ore are reported from the Rambler-Cariboo, Slocan Star mine, Mother Lode, Yankee Girl and others. A body of galena averaging 50 per cent lead and 200 ounces silver was located on the Hidden Treasure claim of the Slocan Star group. A streak of grey copper was also found on the same property. The Lucky Jim zinc mine is once more shipping to American smelters and is trying to arrange for a steady production of 100 tons per day. The company is contemplating the building of a 100-ton concentrator at Kaslo, which would enable it to put out a quantity of its second-class ore. It is pleasing to note that a force of men has been put back into the upper workings at the St. Eugene, Moyie. This property is now shipping about 800 tons of concentrate per month to Trail smelter.

The McGillivray Creek Coal & Coke Company is gradually increasing its output. The new tipple is now working. Electric fans have been installed and work on the new adit begun.

Phoenix.—Considerable comment is being made upon Granby affairs lately, owing to the recent slump in the company's stock, which was caused by adverse reports emanating from the company's officers. Much has been said on both sides of the question and at this date nothing definite has resulted. An engineer who recently made a hurried examination of the property claims they only have about 6,000,000 tons of ore "in sight." The report of this company for the half year ending December 31st, 1909, shows that the smelter treated 572,371 tons of its own ore. At this rate there is five years' ore in sight. But if we understand the situation rightly there are still the factors of probable ore and possible ore to be taken into consideration, and the "personal equation" of the engineer reporting enters into the calculations at this point. Some local mining men state that the company is over-capitalized and cannot earn 8 per cent. Unless the writer's memory fails him, Mr. Lyman A. Sisley, of the "Mining World," who follows these matters closely, has figured that the dividend-paying copper properties of the United States average in the aggregate about 5 per cent. net, so that

it is only fair to compare Granby capitalization on the same basis as the other big copper producers and not on an 8 per cent. basis. We could name several dividend-paying mines in this country that have not more than eighteen months' ore in sight. With these Granby compares very favourably. There is one thing certain, while the officials of the company may not be to blame, and that is that the stock was manipulated on the New York and Boston exchanges. If the insiders had been possessed of doubts they would have sold out quietly, and the thing came on too quickly to be a general rout of the average shareholders. While there are probably only three or four men who know the exact situation, we are inclined to be optimistic here and will have to be shown that all this gossip is true before believing. This company owns a block of ground in a widely mineralized district four miles long and two miles wide and a patch of this, 3,000 feet long and 1,500 feet wide, is all that has been worked so far. The report referred to above shows that it cost the Granby Company for that period $2.86 per ton to mine and treat its ore. It will be agreed that this is fairly low. The cost of copper produced, per pound, was 10.4 cents and the average price received was 13.139 cents. The balance sheet of the company, December 31st, 1909, read as follows: (Assets) Cost land, machinery, etc., $15,505,417; stocks and bonds, $994,822; supplies, $257,544; cash and copper, $801,284; total, $17,559,077. (Liabilities) Capital outstanding, $13,500,000; dividends held, $120,956; cash loan, $875,000; account payable, $97,152; advance on copper, $250,000; surplus, $2,715,969; total $17,559,077.

There is much activity in store for Nickle Plate camp, Hedley this season. The new Rand 2,300-foot compressor is now running smoothly and furnishing a full supply of air for all presen purposes. The 40-stamp mill is treating about 150 tons o ore per day, the mineral content being saved at present b means of amalgam plates, Frue vanners and the cyanide plant An Allis-Chalmers tube mill and a set of Deister tables, witl filter presses, etc., have been ordered, with a view to makin a better extraction. In order that the mining and millin plant of the Daly Reduction Company may be run all the yea round a steam auxiliary plant has been ordered. This will con sist of three 150 horsepower return tubular boilers, a 275 kilo watt generator and a 375 horsepower high speed engine. The generator may also be operated by water power, of which the company has a plentiful supply at certain seasons of the year Motors will be put in the mine and mill and the current from the power plant transmitted to points where it is needed. Much of the machinery in the mill is now operated by independent water wheels, which has resulted in a shut-down in the past when water was scarce. This will be overcome by means of the new plant, which will enable the company to work on a larger and more steady scale.

GENERAL MINING NEWS.

NEW BRUNSWICK.

St. John, N.B., April 16.—At a stormy meeting of directors of Disraeli Asbestos Company yesterday J. M. Healy, treasurer, resigned and two other St. John directors were asked to retire.

Mr. R. D. Isaacs has been away from the city three weeks, but his wife says she expects him back in two weeks.

On Thursday Roch. Gagne, L. A. Codere and F. X. Lebranche, accompanied by their legal adviser, W. Banks, B. F. Campbell and A. W. Warrell, who have considerable interest in the concern, arrived from Sherbrooke, and after holding several meetings and examining the books came to the conclusion that the interests of the shareholders demanded the resignation of Mr. Isaacs, as managing director, and other members of the board residing in St. John.

Their investigation revealed, it is said, the fact that the company, which is incorporated under the laws of the State of Arizona, had not taken out a license to do business either in New Brunswick or Quebec.

The directors declare that the shareholders had no particular occasion for alarm. The irregularities in regard to incorporation of the company could easily be straightened out, and its properties were undoubtedly valuable, and with energetic management could be easily made to yield large returns.

Headquarters will probably be removed to Sherbrooke.

ONTARIO.

Cobalt, April 15.—On the four hundred foot aerial tramway between the Temiskaming rock house and the mill the half-ton skips are now travelling regularly to the hundred ton concentrator on the rise above the Temiskaming and Beaver mines. All last week the mill was running, sometimes ten, sometimes twenty, stamps, but with the additional h.p. permitted, the whole battery of thirty stamps was running.

So far the results obtained have averaged up to tests. Much of the high grade ore that is now being brought to the surface is from the 350 foot level, and in the process of mining it, much low grade is taken out and is passed on to the mill.

Upon another tramway cars are running to the dump and returning to the rock house, where it is fed into the big crusher and passed through the screen, the undersize going directly to the skips and the mill, while the oversize passed to rolls. Nothing above three-quarters inch goes to the mill.

On the top floor of the mill the metallics are taken out in four trommels, three jigs and tables, and before it leaves 65 per cent. of the estimated extraction has been made.

The jig concentrates are running about 3,000 ounces, and the table concentrates between three and four thousand. The motors, both in the mill and the rock house, are now running smoothly, and since the addition of power the stamps have been falling regularly. From now the Temiskaming mill will treat in the neighbourhood of a hundred tons a day.

Sudbury.—The Mond Nickel Company has taken an option on the Mount Nickel locations, belonging to the Great Lakes Mining Company. Two diamond drills are now at work and it is hoped that the continuation of good ore will be found in depth.

The Canadian Copper Company is drilling in the same neighbourhood, between the Stobie and Frood mines.

Wabigoon.—Following are the officers of the Merger Mines, Limited, which is about to commence the development of the famous Laurentian mine in the Manitou:

President—E. E. Hedges.

Vice-President and Treasurer—J. P. Kaiser.

Secretary—John B. Corliss.

Directors—E. E. Hedges, J. P. Kaiser, John B. Corliss, E. R. Warner, and Carl Hoffman, all of Detroit with the exception of Hedges, who is a Boston man.

The capital is 3,000,000, in one dollar shares.

Mr. F. Hille, M.E., has been appointed consulting engineer and will have charge of organizing the forces at the mine.

The new company comes into control of 1,200 acres, which includes, besides the Laurentian, several other properties in great or less stages of development.

A force of men is now engaged in cutting wood and putting things to rights around the mine, though for the matter of that ever since the Imperial Bank closed down on the property it has been carefully looked after. Water was not allowed to accumulate in the shaft and work can be started just as soon as the organization of the working forces has been completed.

BRITISH COLUMBIA.

Nicola.—It is given out that the Nicola Valley Coal & Coke Company's mines at Middlesboro will shortly be producing 1,500 tons of coal daily. A progressive policy of development has been inaugurated and if the C. P. R. provides the cars the maximum output will shortly be reached. At present 300 men are employed, but this staff will steadily be increased.

Two new tunnels are now being bored which will give a greater coal area. These will be completed in a few weeks' time. The company has completed arrangements with Scottish and English capital for the installation of 1,000 coke ovens. The work will not be undertaken until the construction of the Kettle Valley Railway is well under way and there is assurance of early completion. The coke will be shipped to the boundary, where it is thought there will be a splendid market.

The new tunnel in No. 3, which is being built, will connect with No. 2. A new mine is being opened up in No. 1 mine.

In No. 5 mine a 5-foot seam was struck. It is claimed by those who know that it is the finest and cleanest coal yet struck in the camp, there being no indication of any rock whatever.

An electric plant is to be installed this summer which will run the whole works. This is particularly required to move cars from No. 2 tipple to No. 1 tipple. This plant will be sufficiently large enough to furnish Merritt with electricity if the citizens here desire such a much-needed improvement.

Nelson.—At the Mother Lode Mine, Sheep Creek, a promising vein was recently struck on the 300-foot level. The Mother Lode is controlled by Mr. John McMartin, formerly of the La Rose Syndicate.

YUKON.

White Horse.—The holdings of the Yukon-Pueblo Mining Company at White Horse have been purchased by the Atlas Mining Company. The latter company is organized under the laws of West Virginia. The stock is largely held in Spokane. The mine will in future be known as the Atlas.

MINING NEWS OF THE WORLD.

RUSSIA.

From the middle of January last until the present time there has been an almost complete absence of any illuminating oil at Batoum for export abroad and to the inner ports. Tank steamers are waiting in the port for weeks without any chance of their being loaded, as oil comes from Baku in exceedingly limited quantities. Instead of the usual 1,500 to 1,750 tons arriving daily through the pipe-line, scarcely 200 to 250 tons are pumped now. The main reason for this state of things is that the refiners are abstaining from sending their oil until the new reduced tariff comes into force.

NEW ZEALAND.

Wellington, 4th April.—The New Zealand gold output for March amounted to 36,449 ounces, valued at £142,841, as compared with 40,044 ounces, valued at £156,522, during the corresponding month of last year. The silver output for the month was 110,204 ounces, valued at £11,029, as compared with 204,008 ounces, valued at £20,343, during March, 1909.

SOUTH AFRICA.

A co-operative smelting works, of which the various mining companies on the Rand have become members, has been formed, which is likely to prove of considerable convenience to the industry. The blast furnace of the Robinson Gold Mining Company has been taken over, and alterations and additions are being made to enable the new company to begin smelting operations at once.

The Transvaal Coal Owners' Association has effected an arrangement whereby rate cutting has been abolished. The association laboured under the disadvantage that several important properties were not included therein, such as Messrs. Lewis and Marks' Vereeniging undertaking and the Witbank Colliery, the expanding outputs from which were a menace to those who were included in the combination. This amalgamation of interests has long been the desire of the leading financial houses, and we are informed that pending its completion Messrs. Eckstein held back a very substantial contract which has now been placed.

UNITED STATES.

New York, April 15.—Following an announcement yesterday of an increase in pay for employees of the United States Steel Corporation and its subsidiaries, Elbert R. Gary, chairman of the executive committee, made public this afternoon details of a plan for the relief of employees injured at work and the families of men killed. The plan will be put in operation May 1, for a year's test. The cost will be several millions a year and employees do not contribute.

For temporary disablement, single men will receive 35 per cent. of their wages and married men fifty per cent., with an additional five per cent. for each child under 16, and two per cent. for each year of service above five years. For permanent injuries lump payments are provided, based upon the extent to which the injury interferes with employment and the annual earning capacity of the victim.

Where employees are killed, their families will receive a sum equal to his wages for a year and a half, with an additional ten per cent. for each child under 16, and three per cent. for each year of service above five years. In case of injury a period of ten days must elapse before relief begins.

Goldfield, Nev., April 16.—General Manager J. R. Finley of the Goldfield Consolidated Mines Company has given out the following statement concerning the conditions at the big mill, which was damaged by fire last week:

"We hope to have the 80 uninjured stamps of the mill running in about 30 days, which is the very shortest possible time in which arrangements can be made to get ore into the mill. Practically all equipment has been ordered, and as fast as it comes in all the men that can be worked on reconstruction will be busy. A big force of men is now engaged in clearing away the wreckage where it is not too hot to handle. Of course there will necessarily be some curtailment of mining operations, but this is only on the ore extraction end. We have no place to put the ore now. But the force working on development will be largely increased. We will endeavour to find a place for every man employed by the company, and will use many of the men who are out of their regular work by the stoppage of the mill in helping clear away the debris and in reconstruction work."

Ely, Nev., April 13.—It is officially announced that the plant of the International Smelting & Refining Company at Tooele, Utah, will be ready to receive ores by about the middle of May. By that time, or not long thereafter, the Giroux Company should be able to ship high grade ore from the lower levels of the Alpha shaft if the management desires to do so.

Globe, Ariz., April 13.—The Detroit Copper Company has filed an answer to the complaint of the Mine & Smelting Supply Company, which charges the mining company with purchasing ore concentrates which infringe on the Wilfley patents. The answer is a general denial of all material allegations in the complaint of the defendants, stating that it has no knowledge that Arthur R. Wilfley was the first and sole inventor of the ore concentrator or that these improvements have gone into great and extended use and have displaced or superseded to a great extent all other apparatus and means for ore dressing by concentration. The company also denies that it purchased any concentrators containing and embodying the invention set forth in the complaint.

A showing also is made in the answer that the making and using of concentrating tables is an old and well known art patented and used in many forms before Wilfley's time and cites letters patent from that of Baran No. 35,197, granted in 1862, to that of Pike No. 586,534, in 1896, while the Wilfley patent was issued as No. 490,675 and was for "narrow and specific improvement in an old art."

The answer is signed by Robert S. Taylor, counsel for the defendant, E. E. Ellinwood, and W. K. Flora. Mr. Taylor is chairman of the committee on patent law of the American Bar Association, and has been retained by the Deister Concentrator Company to defend the suits brought against companies purchasing the Deister concentrators.

COMPANY NOTES.

CALUMET AND HECLA.

The report of the Calumet & Arizona Mining Company for 1909 shows total receipts of $5,054,664, as compared with $4,204,608 for the year 1908. Dividends paid amounted to $800,000, which was the same as in the previous year. Cash on hand at the end of 1909 was $813,360, as against $73,259 at the end of 1908. The company produced 27,630,050 pounds of refined copper in 1909, as against 28,048,329 in 1908. The average price received was a trifle over 13 cents a pound, as compared with a little less than 13 cents in 1908. The gold and silver produced during the year amounted to $211,760, as compared with $234,358 in 1908.

DIVIDEND ON KERR LAKE.

Kerr Lake directors on April 13th declared regular quarterly dividend of 25 cents per share, and 25 cents extra, payable June 15, to stockholders of record June 1.

PROFITS OF B. C. COPPER COMPANY.

The returns of the British Columbia Copper Company for January and February of this year, operating in the Boundary district, indicate net profits of $73,500 for the two months. The copper output was 1,339,707 pounds, with 15,151 ounces of silver and 5,073 ounces of gold. After crediting these gold and silver values the company was able to lay copper down in New York refined at a cost of less than eight cents per pound. The production follows:

	Jan.	Feb.
Copper, lbs.....	656,573	683,234
Silver, ounces	7,530	7,627
Gold, ounces	2,513	2,560

The returns from the smelter for the first three months of the year indicate approximately the same amount of ore reduced as in the corresponding months in 1909, but the gold and silver values have been running higher this year. It is expected that when ores from the Jackpot mine will be treated, a still greater increase in gold and silver values will be shown.

It is probable the work of enlarging the reduction works will commence immediately, increasing its capacity to about 3,000 tons per day. By the time the enlargement shall have been completed the company will likely have controlling representation on the directorate of the New Dominion Copper Company, whose mines are being got in readiness.

The McKinley-Darragh Cobalt Mine's report for the year ended December 31 last shows a total surplus of $120,687, an increase of $74,000.

ANNUAL MEETING DOMINION COAL COMPANY.

The Dominion Coal Company's annual meeting was held in Montreal on April 12th. President Plummer's statements were well received and no animus was shown.

In answer to questions Mr. Plummer gave it as his opinion that the merger would assuredly benefit shareholders in both companies.

After the report had been read and adopted, the President expressed his gratification at the fact that the new board had been able to accept the figures prepared by the old management without change. He also called the shareholders' attention to the fact that the falling off in the year's earnings was due entirely to the strike. He advised that the shareholders should not be discouraged by the report. They had a property in excellent condition, he said, and with established earning power. Only patience was needed, with present difficulties, before the company emerged from its troubles and entered once more upon a season of prosperity.

The company's real earning power, according to Mr. Plummer, should be based upon the earnings of the last previous unbroken year rather than upon that for the past year, when the company had been hampered and its output curtailed by serious difficulties. The policy of this new board would be to treat the shareholders with absolute frankness and to let them at all times know the exact facts.

The dispute with the Steel Company was referred to feelingly by the president who declared that he sincerely hoped that this would be the last time it was ever mentioned in an annual meeting of the Coal Co. There was a sum of $3,550,000 to be paid to the Steel Company under the decision. This was not dead loss but merely meant the repayment of a sum which had been held outstanding, and refunded when the decision was announced.

The strike was largely responsible for the heavy loss which had led to the bond issue.

Since the report had been issued two or three matters had taken up the Board's time. One was the question of the price which the Steel Company was to pay for the coal supplied. This had finally been fixed at $1.55 per ton. Mr. Plummer said that this price left a margin of profit above the cost of production.

One good result of the dispute was that the ground had been cleared and the companies were now on a definite working basis.

The normal output of the company at this time of year was 10,000 tons per day. This was the present output also. Later in the year the output increased considerably.

The total yearly output might easily be increased to 4,000,000 tons, and it was the aim of the board to accomplish this.

Whatever agreement might finally be made, the proposals would have to be submitted to both boards. The supposition had gained ground that the Steel Company could force the Coal

Company into a merger against the wishes of the Coal shareholders. Mr. Plummer pointed out that some forty or fifty thousand shares would have to accept the terms. He thought that this clause fully protected the Coal shareholders.

Many conditions there were that made it very difficult to come to an agreement. There was no way out unless both sides were prepared to give and take. Immense benefits would accrue to both companies if such an agreement became an accepted fact.

The earnings of both companies were substantial. The earnings of the Steel Company would no doubt be less in some years to come and also in other years would be more. The same thing was true of the Coal Company. The alliance of the two companies and the uniting of the earnings would have a balancing effect, the value of which could not be overestimated.

Mr. Plummer here made an interesting comparison of the two companies' assets. Excluding ore deposits, the values of which were very difficult to determine, the assets of the Steel Company are $20,000,000; of the Coal Company $12,000,000.

The new plants of the Steel Company would increase the company's earning capacity thirty per cent. On the other hand, there was to be considered the removal of the steel bounty and other depreciation, which would imply a loss for the Steel Company of from $225,000 to $230,000 yearly.

A resolution supporting the board in its determination to hold out against the demands of the U. M. W. A. in the strike was unanimously adopted. Mr. M. J. Butler, the general manager, presented some figures on the present conditions in regard to the strike. He was at the present time some 1,350 men short, but he was replacing these every day with new arrivals.

There were elected to the Board of Directors Col. James Mason, of Toronto, representing Toronto shareholders, and Sir William Van Horne, to represent the Steel interests.

STATISTICS AND RETURNS

INTERNATIONAL COAL COMPANY.

Shipments, March, 1910	22,115 tons.
Shipments, March, 1909	22,848 tons.
Decrease, March, 1910	733 tons.

Shipments, March, 1910	29,218 tons.
Shipments, March, 1909	21,474 tons.
Increase, March, 1910	7,744 tons.
Shipments, 3 months, 1910	103,565 tons.
Shipments, 3 months, 1909	81,247 tons.
Increase, 3 months 1910	22,318 tons.

MARITIME COAL, RY. & POWER COMPANY.

Shipments, March, 1910	14,851 tons.
Shipments, March, 1909	8,540 tons.
Increase, March, 1910	6,311 tons.

B. C. ORE SHIPMENTS.

The ore shipments and smelter receipts for the week ending April 9th are well up to the average for the year. Appended are the details:

Boundary.

	Week.	Year.
Granby	24,432	355,885
Mother Lode	9,500	125,805
Oro Denoro	350	4,130
Snowshoe	3,114	52,790
Total	50,002	713,710

Smelter Receipts

Granby	24,432	356,005
Cons. Co.	9,566	141,315
B. C. Copper Co.	9,850	129,935
Total	43,848	627,255

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending April 15, and those from January 1, 1910, to date:

	April 15. Ore in lbs.	Since Jan. 1. Ore in lbs.
Buffalo	62,650	585,178
City of Cobalt	.....	300,445
Chambers-Ferland	64,300	122,300
Cobalt Central	.....	205,186
Cobalt Lake	64,000	196,000
Cobalt Townsite	68,000	68,000
Colonial	.....	107,260
Coniagas	.....	434,096
Crown Reserve	83,800	1,591,370
Drummond	.....	664,200
Hargraves	.....	41,800
Hudson Bay	.....	123,695
Kerr Lake	238,444	2,157,523
King Edward	.....	134,506
La Rose	331,820	3,814,070

McKinley-Darragh	148,550	873,991
Nipissing	208,631	3,161,635
O'Brien		453,006
Peterson Lake		170,450
Right of Way		509,717
Silver Cliff		66,010
Temiskaming		238,300
Trethewey		254,650
Waldman		63,992

Ore shipments for week ending April 15 were 1,270,196 pounds or 635 tons.

Total shipments from January 1 to April 15 were 16,337,380 pounds, or 8,168 tons.

NOTICE

STUDENTS EMPLOYMENT REGISTER,

The CANADIAN MINING JOURNAL has opened an employment register for students taking mining or metallurgical courses at Canadian Universities or Technical Colleges. Mine operators who wish to employ students during the summer months are requested to communicate with the Business Manager.

Students are requested to send in their names, along with brief records of experience. These will be filed and no effort will be spared on our part to place applicants in immediate communication with possible employers.

The Nissen Stamp

In Cobalt

NORTHERN CUSTOMS CONCENTRATORS, LIMITED.
COBALT, ONT., December 31st, 1909.

The Canadian Fairbanks Co., Toronto, Ont.

Dear Sirs :—

In answer to your enquiry regarding the Nissen Stamps supplied by your firm. These stamps are running steadily on some of the hardest rock on the Continent, they are crushing 5.3 tons of ore per head in twenty-four hours. The feed rolled down to go through about a one-inch hole.

The screen used for the above tonnage was 30 x 30 mesh, 28 gauge wire, opening .018. With a coarser screen the tonnage would of course be larger.

The shoes and dies wear even, and the splash is well distributed over the screen.

The arrangements for keeping up the weight of the stamps are very good. I can recommend the Stamps.

Yours truly, (Sgd.) F. J. Bourne, Superintendent.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining ngineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show gns of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a orough knowledge of Mining Law, should be very careful with whom they place their business.

GEOLOGICAL SURVEY

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, and with many local areas and special subjects.

MARITIME PROVINCES

The whole of Cape Breton, and a large portion of the coal and gold fields of Nova Scotia, have been reported upon, and mapped on a scale of 1 mile to 1 inch. The remaining portions of the Province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter Provinces, mapped on a scale of 4 miles to 1 inch.

QUEBEC

Quebec, south of the St. Lawrence, has been reported upon, and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the Province north of the St. Lawrence are also available.

ONTARIO

A large part of the Province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

THE PRAIRIE PROVINCES

Geological maps and reports have been issued covering the greater part of the Provinces of Manitoba, Saskatchewan, and Alberta.

BRITISH COLUMBIA

The southern portions of British Columbia, as well as other parts of the Province, have been reported upon and mapped.

YUKON

Many of the important areas in the Yukon have been reported upon and mapped.

THE NORTH WEST TERRITORIES

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of a report or map will be sent to Canadian applicants free of cost, and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

Applications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.

THE FOLLOWING GEOLOGICAL MAPS HAVE RECENTLY BEEN ISSUED:

CANADA

1084. General Geological Map of Canada. Scale 100 miles to 1 inch.

NOVA SCOTIA

1019. City of Halifax Sheet.
1025. Waverley Sheet.
1037. Windsor Sheet.

The above sheets belong to the regular series of Nova Scotia map sheets on a scale of 1 mile to 1 inch. The first includes Halifax City and Harbour, the second the Waverley Gold District, and the third Gypsum Quarries.

ONTARIO

1023. Geological Map showing position of Corundum-bearing rocks in Central Ontario.
1076. Gowganda Mining Division.

This map besides representing the geology of the Gowganda area, represents the geography of a considerable area to the east and north.

980. Portion of Algoma and Thunder Bay districts, Ontario, 1908. W. J. Wilson.
1081. Region lying north of Lake Superior between the Pic and Nepigon Rivers, Ontario, 1906. W. H. Collins.

BRITISH COLUMBIA

1002. Geological Sheet, Special Map of Rossland.

This map, on a scale of 400 feet to 1 inch, besides accurately indicating the topographical and cultural features, shows the geology and location of veins.

1004. Geological Sheet, Rossland Mining Camp. Scale 1200 feet to 1 inch.
1074. Sketch map of Sheep Creek Mining Camp, West Kootenay, B.C., scale 1 mile to 1 inch.

YUKON

1041. Geological and Topographical Map of Whitehorse Copper Belt. Scale 1 mile to 1 inch. Also several detail maps of same belt.

NOTE.—Maps recently published may be had on linen cloth, for use in the field, at 10c. per copy.

REPORTS

1072. Summary Report of the operations of the Geological Survey for year 1908.
1085. Descriptive Sketch of the Geology, and Economic Minerals of Canada. G. A. Young. Introduction, R. W. Brock.
1075. Gowganda Mining Division, 1908. W. H. Collins.
1035. Coal Fields of Manitoba, Saskatchewan, Alberta, and Eastern British Columbia, 1908. D. B. Dowling.
1050. Whitehorse Copper Belt, Yukon. R. G. McConnell.

NEW CATALOGUE

1073. Catalogue of Publication 1843—1909.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are: Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows:

All mines belong to the Goverment of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unserveyed territory, is open to prospecting.

Miners' Certificates good for a calendar year may be obtained by sending $10.00 to the Department of Mir es. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minium being 40 acres in unserveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of $10.00 plus a yearly rental of $1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed territory may be purchased as a mining concession at the price of $20.00 per acre if within 20 miles of a railway in a straight line, or $10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

The Hon. Minister of Colonization, Mines and Fisheries
Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

General Passenger Department, Intercolonial Railway

MONCTON, N.B.

We illustrate the Hecla Mining Company's Hoisting Plant at Burke, Idaho, one of the largest of its kind and a good example of

The Westinghouse Equalizer Hoisting System

Some particulars of the installation follow:

The hoist motor is a Westinghouse 450 h. p., 600 Volt, 60 R.P.M. Direct-Current Motor, which obtains its power through a Westinghouse Fly-Wheel Motor—Generator Set, consisting of a 450 h.p., 2300 Volt Type H. F. Induction Motor, a 30,000 lb. Fly Wheel and a 450 K. W., 600 Volt, Direct Current Generator. The normal duty of the hoist is 6,000 lbs. unbalanced load; maximum speed 2,000 R.P.M. ultimate depth of shaft 2400 feet.

Three Post Magneto Electric Blasting Machine

NOBEL GELIGNITE

It always breaks cleanly to the bottom of the drill holes and is free from fumes of any kind. Equal to 75% Dynamite and is sold at a price producing very much better results in terms of Rock Broken or Extracted and money spent.

"WINTER BRAND" DYNAMITE

Is only one strength, if anything, a little stronger than 50% Dynamite. **It does not freeze,** or rather, explodes with perfect efficiency when frozen **and needs no thawing.**

"AUTUMN BRAND" DYNAMITE

Is packed in all the usual percentages. The powder is similar in appearance, character and effect to ordinary Dynamite, except that the freezing temperature of the Nitro-Glycerine is reduced from 42° F to a little under 30° F.

PERMITTED EXPLOSIVES for Coal Mines
Nobel Monobel, Saxonite and Carbonite.

"CLEVELAND" STOPE DRILLS

EFFICIENCY:—Of course you want the stope drill which has the highest efficiency, but you must pick out the one that will have as high an efficiency a year from to-day. Isn't it true that your stope drills decrease steadily in efficiency as they grow older?

REPAIRS:—Repairs which must be made from time to time after the part has given long and satisfactory service, are not a source of dissatisfaction, but dont you find that your stope drills are constantly needing something new?

DRILLING CAPACITY:—As long as your stope drill will put in sufficient holes per shift to drill up your stope there is no argument in favor of your changing to our drill just becanse it will drill faster. We know that. But we know that the "CLEVELAND" Stope Drill will do as much work per shift when it is one year old as it will when one week old, and that is what you want, isn't it?

THE "CLEVELAND" Whether you purchase your stope drills after considering efficiency, repair cost, or drilling capacity, the "Cleveland" should be the stope drill you specify, for its design is such that the initial efficiency is the highest possible in an air tool, and the piston and valve action are so related that the "Cleveland" is just as efficient when it is a year old as when it is brand new; we **know**, and our information is gained from hundreds of installations that the "CLEVELAND" will cost less for repairs **per year** than any stope drill made; a 30 day trial will convince you that the "CLEVELAND" will drill as much per shift as any other stope drill, and we have machines always in stock ready to ship for trial if you will drop us a line, As you have everything to gain and nothing to lose, why not investigate NOW?

Amatite ROOFING

NEEDS NO PAINTING

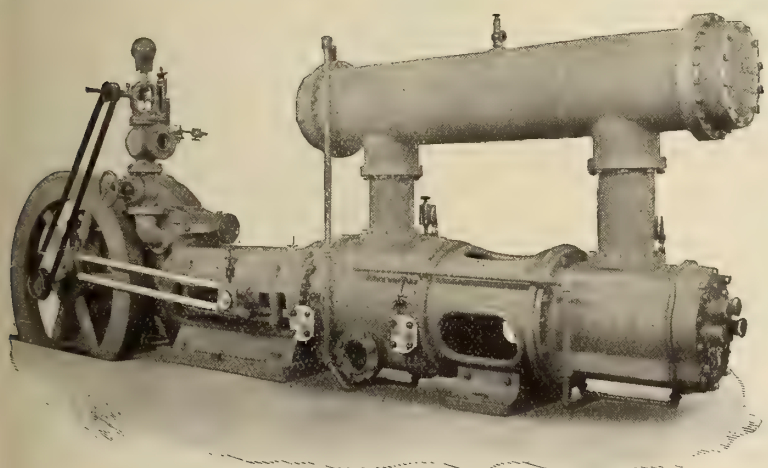
MOST ready roofings require special painting and coating, and unless this is done regularly, you are sure to have leaks and trouble right along.

If you use Amatite, nothing of the sort is required. You will have real roof protection *without painting* of any kind.

Amatite is made to stay waterproof and give protection year after year, without any thought or care on your part.

First—Because it is waterproofed wtth Coal Tar Pitch.

Second—Because it has a real Mineral Surface.



Amatite, owing to these features, is the most economical roofing made. Its first cost is low, and you are *saved* all future expense for repairs or paint because it will need neither.

If you haven't seen Amatite, write for a sample to-day. From it you will very quickly understand why it doesn't require painting; why it does not leak; and why it saves you money.

Address nearest office to-day.

The Davis Handbook

OF THE

Cobalt Silver District

By H. P DAVIS.

ILLUSTRATED WITH PHOTOGRAPHS

¶ The first section of this volume is an outline on the Geology, Mining Treatment and Marketing of the Ores of the Cobalt District, the object being to give all the data and general information necessary to guide investors, brokers and professional men generally.

¶ Included in this volume is a complete and accurate directory of all mining companies operating or organized to operate in the Cobalt Silver District of Ontario.

¶ Full information as to capitalization, directorates, locations and conditions of properties is given. Tabulated statements of production and dividends revised up to January, 1910, are included.

PRICE $1.50 PAPER COVER $2.00 STIFF COVER

BOOK DEPARTMENT

Canadian Mining Journal

TORONTO

A New, Complete and Authoritative Treatise.

Cyanide Handbook

By J. E CLENNELL.

Over 500 pages, 6x9, illustrated, $5.00 (21s) net, postpaid.

Mr. Clennell has been in close touch with the rapid developments of cyaniding. He has been instrumental, too, in many important discoveries, and his work in this field has taken him to the leading plants of the world. It deals generally with Cyanide and does not confine itself to the process alone. It is divided into nine main parts covering the subject more fully and exactly than it has heretofore been handled.

Especially noteworthy is the full treatment of recent developments and important phases heretofore *inadequately treated.*

CONTENTS

Part I. General.

Introduction.—I. Early History of the Cyanide Process. II. Outline of Operations in the Cyanide Process.

Part II. Chemistry.

THE KING.

When on the evening of Friday, May 6th, the news reached Canada that King Edward VII. had passed away, incredulity was succeeded by dumb sorrow. The blow was cruelly sudden—so sudden, indeed, as to be dazing.

Now the whole Empire over which Edward the Peacemaker ruled so well is plunged in sincerest grief.

Canadians have special reasons to revere the memory of King Edward. During his peaceful reign Canada has prospered as never before. Our industries have flourished. Our commercial life has expanded most notably. In all respects we are a stronger, more united, and infinitely more confident nation than we were ten years ago.

In large measure King Edward's unfailing tact, clear judgment, and strength of character made possible our progress during the last decade. A less wise monarch might have sanctioned the popular clamour for war. Fortunately for us, the monarch whose death we lament devoted all the prestige of his high office and all his rare personal abilities to the cause of peace.

Canadians will ever remember with unchanging affection the brief reign of King Edward VII. His successor, King George V., may confidently count upon Canada's unswerving loyalty.

THE McKINLEY-DARRAGH-SAVAGE REPORT.

Not altogether illuminating is the usual mine manager's annual report. Not infrequently the manager regards his report as a superfluous duty that can readily be scamped. He writes a page or two of disjointed narrative with a few figures interspersed—and sighs a sigh of relief.

To many competent managers writing is an affliction. To others it is a means of disguising thought. All too rare is the manager who writes fully and appropriately the record of his year's work.

The report under consideration is a model. It is concise, interesting, informing. It is suitably illustrated. No important detail is omitted. The arrangement is logical. In brief, the McKinley-Darragh-Savage report is as nearly as possible just what a report should be. Before glancing at a few of its more striking features we must proffer our congratulations to Mr. P. A. Robbins, the general manager, to whom the credit of authorship is due; and to the company, whose directors are sufficiently enlightened to authorize the relatively large expenditure that such a report implies.

Mr. Robbins opens his report with a general tabular summary of silver produced and silver shipped during the past four years, and a general statement of costs for the year 1909. We notice that a total of 2,722,992.64 ounces of silver has been produced in the period 1906-1909, inclusive. As set forth under "Expenditures for Operations," the total cost per ounce of silver produced is 17 cents—a very creditable figure in view of the limiting conditions that affect the McKinley-Darragh. Under "Operations," Mr. Robbins includes all costs for shaft sinking, timbering, cross-cutting, raising and other development work. If these items were charged to capital expenditure as development, and this is the usual practice, the cost per ounce would be reduced to 14 cents. Mr. Robbins' method is to be commended.

A particularly interesting table is that giving itemized marketing costs. Of the five items—consular fees, insurance, freight, sampling, and smelter charges—the last is by far the heaviest, amounting to 4 cents per ounce. The total marketing cost is 5.3 cents per ounce.

The estimates of ore reserves, 110,300 tons, containing 5,725,000 ounces, are given in round numbers. Here Mr. Robbins avoids the meaningless refinement of arithmetic whereby reserves are estimated down to the odd ounce or even to a fraction of an ounce.

In dealing with the accidents that occurred during the past year, a careful classification as to causes is followed; and the resulting injuries are specified. This is not only sound engineering practice, but it is also good citizenship. Were this policy followed by all Canadian mine managers, there would be fewer accidents.

The extent and distribution of underground work Mr. Robbins sets forth fully. The amount of stoping is reported in cubic yards. The amount, also, of trenching is reported.

Commenting upon the character of the rock, the manager states that a man and helper in one shift of nine hours, using a 3 1-8 inch drill, will drill 25 to 30 feet in conglomerate, 30 to 35 feet in lower Huronian measures, and from 35 to 45 feet in slates, all holes being about five feet deep. The average charge of powder is about 2.1 pounds of 60 per cent. dynamite. The number of holes required for breaking a face, 5 feet 6 inches by 7 feet, varies from 9 to 13, according to the rock, the conglomerates being the toughest.

The mining, milling, and general charges are carefully analyzed. The wage schedule is given. We note that $2.25 per day is the lowest rate obtaining. Drill runners are paid $3.25 per day. The cost of supplies, such as meat, coal, lumber, and dynamite, appears on page 11.

Following this general information, the work done in each vein is stated, and provisional estimates of the reserves on each are furnished.

We could readily continue culling from Mr. Robbins' report, but space will not permit. Many items of interest we must be content to omit. Our readers will find the report reproduced almost in its entirety on other pages of this issue.

The coloured maps, the diagrams, plans, and tables imply an immense amount of labour. The general text gives evidence of a critical choice of words and more than usual facility in condensation. In fact, Mr. Robbins has begun and ended his task with the clear intention of telling his directors and shareholders everything that they have a right to know. And he has succeeded in doing this within most reasonable limits.

We sincerely hope that our readers, especially those readers who happen to be mine managers, will study thoroughly the McKinley-Darragh report. Time thus spent will not be lost.

CONSERVATION AND COMMON SENSE.

On several occasions we have emphasized the fact that our sympathies are strongly with the work of the Conservation Commission. The desirability of educating the nation up to a point where ruthless waste of nature's bounties will be looked upon as a crime is beyond question. But so far as we have been able to observe, the personnel of the Commission leaves much to be desired.

In the first place, the Commission is not composed of men who possess first-hand knowledge of the resources to be conserved, or, rather, to be used economically. Lumbermen, farmers, and miners are, naturally, the persons who respectively possess the most intimate knowledge of the three basic industries. Yet not one of these industries is represented on the Commission. We should like to know the reason for this. Are lumbermen, farmers, and miners not to be trusted? Are they uniformly robbers and plunderers? Or are they ignorant children who, forsooth, must be led by the hand?

In one other respect the Commission must be criticized. The word "conservation" has become a shibboleth. The unthinking take it for granted that the present generation is the only one that has attacked the problem of utilizing properly the country's natural wealth. This, of course, is far from the truth. The fact is that "conservation" is merely a new label. In Canada, for instance, the Geological Survey and other Government bureaus have been engaged in the work of collecting and disseminating information for the last sixty-five years. And much of this information has had to do, either directly or indirectly, with various phases of conservation. The records and reports of the Geological Survey, for instance, constitute an almost exhaustless mine from which the Conservation Commission cannot do better than draw.

As we have remarked above, "conservation" is merely a new label. In all essentials the lumberman, the farmer, and the mining engineer (we mention these classes merely for illustration) have been and are becoming more and more the exponents of practical con-

ervation. Every improvement in lumbering, farming, nd mining implies a definite addition to the wealth of he nation. Every method devised for the utilization f waste products, such as sawdust, mechanical fertiliz-rs, slag, creates new wealth and postpones the final lepletion of our sources of raw material. In other words, our workers, our engineers, are essentially conservers.

We must conclude, therefore, that the Commission must guard against ineffective teaching or preaching; and must recognize that its real end is to supplement the efforts of others by giving timely and proper publicity to facts, figures, and ideas that are not available to the masses. Another important function, one that the Commission is not at present qualified to perform, is the promotion of restrictive legislation. Unless the membership of the Commission be made more representative, any attempt to formulate new laws will be utterly vain.

THE TIMMINS SAMPLE CAR.

It is by no means an easy matter to place in its proper light the meaning of a sample, whether that sample be made up of a few pounds of ore or consists of one or more carloads. Other things being equal, we are apt to accept results obtained from large samples more readily than those obtained from small lots of ore. However, mere bulk is no guarantee of accuracy.

The Porcupine gold fields are much in the public eye at present. Among the pioneers of Porcupine were the Messrs. Timmins and Dunlop. These gentlemen, by the way, signalized their confidence in Porcupine by paying a very large cash price for certain claims. From workings on these claims there was recently taken a sample carload of ore. The entire car of ore was crushed, sampled, and assayed by competent specialists in the United States. The assay value of the ore is reported as being $202.75. This, of course, is most gratifying. But there is distinct danger of overemphasizing this particular assay report.

While we do not doubt in any way the "bona fides" of the men who took the sample, yet there is every likelihood that the carload was, to some extent at least, selected ore. The taking of an absolutely fair sample is neither a simple nor an easy matter. Very few men, indeed, are qualified by experience, or fitted temperamentally, to undertake the sampling of a gold-bearing vein. But, granting that the announced results are probably too high to be really representative, yet there is ample reason for encouragement. The fact that a carload of such rich ore could be secured in restricted workings and with no conscious effort on the part of the samplers to select the rich and reject the lean, is a pleasant surprise.

EDITORIAL NOTES.

The Yukon dredging season has had the earliest opening on record. Dredge No. 1 of the Canadian Klondike Company was put in commission on April 27th. Water is plentiful. Everything points to a prosperous year.

PERSONAL AND GENERAL.

Mr. S. N. Graham is paying a professional visit to Cobalt.

Mr. R. W. Brigstocke has been elected a member of the Institution of Mining and Metallurgy.

Mr. R. G. Drinnan has been engaged to examine and report upon coal lands on Graham Island, Queen Charlotte, B.C.

Mr. Martin Nordegg has returned to Toronto. For the last four months Mr. Nordegg has been travelling through Egypt and Turkey.

The sympathy of our readers will be extended to the veteran editor of the Transactions of the Canadian Institute, Dr. George Kennedy, whose wife died on Friday, May 6th.

Mr. J. B. Tyrrell has been elected president of the Canadian Institute, the oldest scientific society in Canada. The Canadian Institute was organized in 1849. Among the former presidents were Sir William Logan, Sir Henry Lefroy, Sir John Beverly Robinson, Hon. G. W. Allan, and Sir Sandford Fleming.

A special coal dust experiment station is used by the Vienna Committee on Fire-Damp for studying mine explosions. A masonry gallery 964 feet long has an arched roof about 7 feet high, increasing slightly in height toward the outer end, and is covered with earth varying in depth from 6 1-2 feet at the outer end to 70 feet over the explosion chamber. This chamber, forming the inner end of the gallery, is of concrete, 6 feet high, 6 1-2 feet long, and 4 1-2 feet wide. Racks of shelves for coal dust are placed at intervals along the gallery, and apparatus is provided for testing measures for preventing and limiting explosions, such as wet zones, water sprays, and zones of stone dust. The flame produced by an explosion is measured by matches placed along the gallery at intervals of forty inches. Loosely corked bottles, filled with water, are suspended bottom up about 35 feet from the explosion chamber, and strings attached to the nearest shelves draw the corks when the shelves are moved by an explosion. In this way the bottles are emptied of water, samples of gas from the explosion taking its place, ready for chemical and other examination.

The market for Baku petroleum covers Central Russia and the East. Maikop, the newly-discovered oilfield, will probably supply Western and Southern Russia and may export its oil for foreign consumption.

In the Maikop oilfields bluff exposures of oil-bearing strata, sometimes 150 feet vertical measurement, are covered with soft asphalt, the result of oxidation of the exuding petroleum.

There are 9,700 stamps in commission in the Transvaal. The number of gold producers is 68.

THE McKINLEY-DARRAGH-SAVAGE MINES OF COBALT LIMITED.

ABSTRACT OF GENERAL MANAGER P. A. ROBBINS' REPORT FOR THE YEAR 1909.

[Editor's Note.—Mr. Robbins' report has been so carefully compiled and presents so many facts, not only concerning Cobalt, but also of interest from the mining engineer's standpoint, that we have thought it well worth while to reproduce the greater part of it in these columns.]

OUNCES OF SILVER PRODUCED.

	1906	1907	1908	1909	TOTAL TO JAN. 1, 1910
McKinley-Darragh,	42673.07	706543.48	653590.38	1235340.37	2638156.30

TOTALS,	$18737.69	$33186.18	$51923.87

Further analyses of costs will be found in the fo lowing pages, included in the reports on the respectiv properties.

Reduction in Costs.

The year 1910 will see our working costs reduced m terially. With a cheap source of power available, larger production of ore from McKinley-Darragh, th Savage emerging from a phase of development to on of steady, profitable production, and a more settle condition of affairs generally, the results are certai to be congratulatory.

Ore Reserves.

Our ore reserves have been increased by the year work, and in the following reports you will find the estimated as at January 1st:

McKinley-Darragh . 100,000 tons carrying 4975000 oz
Savage ..... 10,300 tons carrying 750000 oz
Total ....110,300 tons carrying 5725000 oz

Prospecting.

During the year our prospectors located a numbe of claims at Gow Ganda and Shining Tree. We hav a controlling interest in eleven claims, upon one which showings of native silver have been found, an upon several others smaltite and cobalt bloom.

Accidents.

Two fires occurred during the year, i e., No. 3 Shaft ouse at the Savage, and the Hungarian quarters at IcKinley-Darragh.

No serious accidents occurred to machinery or plant.

It is with regret that I report three fatalities which ave marred the year's work, all on McKinley-Darragh.

Besides these fatalities there have been a number of inor accidents, which have been catalogued—first, according to causes; second, according to resulting inuries.

Summary of Injuries.

njuries to head and face—16 cases (including 4 cases of eye injuries).
njuries to hands—15 cases (3 cases entailing loss of digits.)
njuries to feet and ankles—5 cases.
njuries to body—4 cases.
njuries to limbs—3 cases.

Typhoid.

Although Cobalt and the camp in general suffered reatly during the autumn from a severe epidemic of yphoid, we were extremely fortunate in not having a ingle case develop upon either the McKinley-Darragh r Savage claims.

Smallpox.

One case of small pox occurred on McKinley-Darragh, having been brought in by an arrival from England. An isolation camp was built under the Medical Health Officer, and the spread of the disease prevented. All costs in connection with the matter were met by us, neither the town nor township contributing.

General.

The character of the ground may be somewhat judged from the following notes:

Using a 3⅛-inch drill, a man and helper in one shift of nine hours, when working on company account, drifting or crosscutting, will drill from 25 to 30 feet in conglomerate, 30 to 35 feet in lower Huronian meameasures, and from 35 to 45 feet in slates under the swamp, all holes approximately 5 feet deep.

The average charge of powder is approximately 2.1 pounds of 60 per cent. dynamite per hole.

The number of five-foot holes required for breaking a face, 5 ft. 6 inches by 7 feet varies from 9 to 10 in the Swamp drifts, 10 to 12 in lower Huronian, and 11 to 13 in the tougher conglomerates of the Blind Vein.

With two faces to work in, so that the drill runners do not have to do their own mucking, one drill working 13½ shifts per week, will, in that time, advance from 18 to 20 feet in conglomerate, 22 to 24 feet in lower Huronian, and 25 to 35 feet in slates.

The foregoing figures represent what is considered fairly good work upon the part of our men.

Milling, - - - - - - - - -	37134.32	2.2072	1.9854	0.0300
TOTALS, - - - - - -	$151442.88	$9.0016	$8.0972	$0.1226

Ore hoisted from mine during year.....16824 tons.
Ore milled .....18703 tons.
Ounces of silver produced.....$1,235,349.37

During the year approximately 10,000 tons of waste rock have been hoisted from the mine. Including this tonnage with the tonnage of ore, the costs work out:

General charges.....$1.064 per ton of rock
Mining .....3.197 per ton of rock
Assume Milling .....1.30 per ton of rock

This is indicative of what could be expected if we were to stop all exploratory work and limit our operations to the mining and milling of ore. In fact, were

we to pursue such a course, it is probable that the total cost of operations could be reduced to $5.25 per ton, for the costs of surface trenching, and other contributing costs could also be eliminated.

A day's work consists of 9 hours, in the mine; 9½ hours, on the surface; and 12 hours in the mill.

The average number of men employed upon operations at the mine, exclusive of construction work, has been 112.

The standard rates of wages are:

Surface Labourers	$2.25	per day
Drill Runners	3.25	per day
Drill Helpers	2.75	per day
Mine Labourers	2.50	per day
Mill men	2.25 to 3.25	per day
Mechanics	2.75 to 3.25	per day
Mechanic's Helpers	2.25 to 2.75	per day

The men are charged 60 cents per day for bed and board.

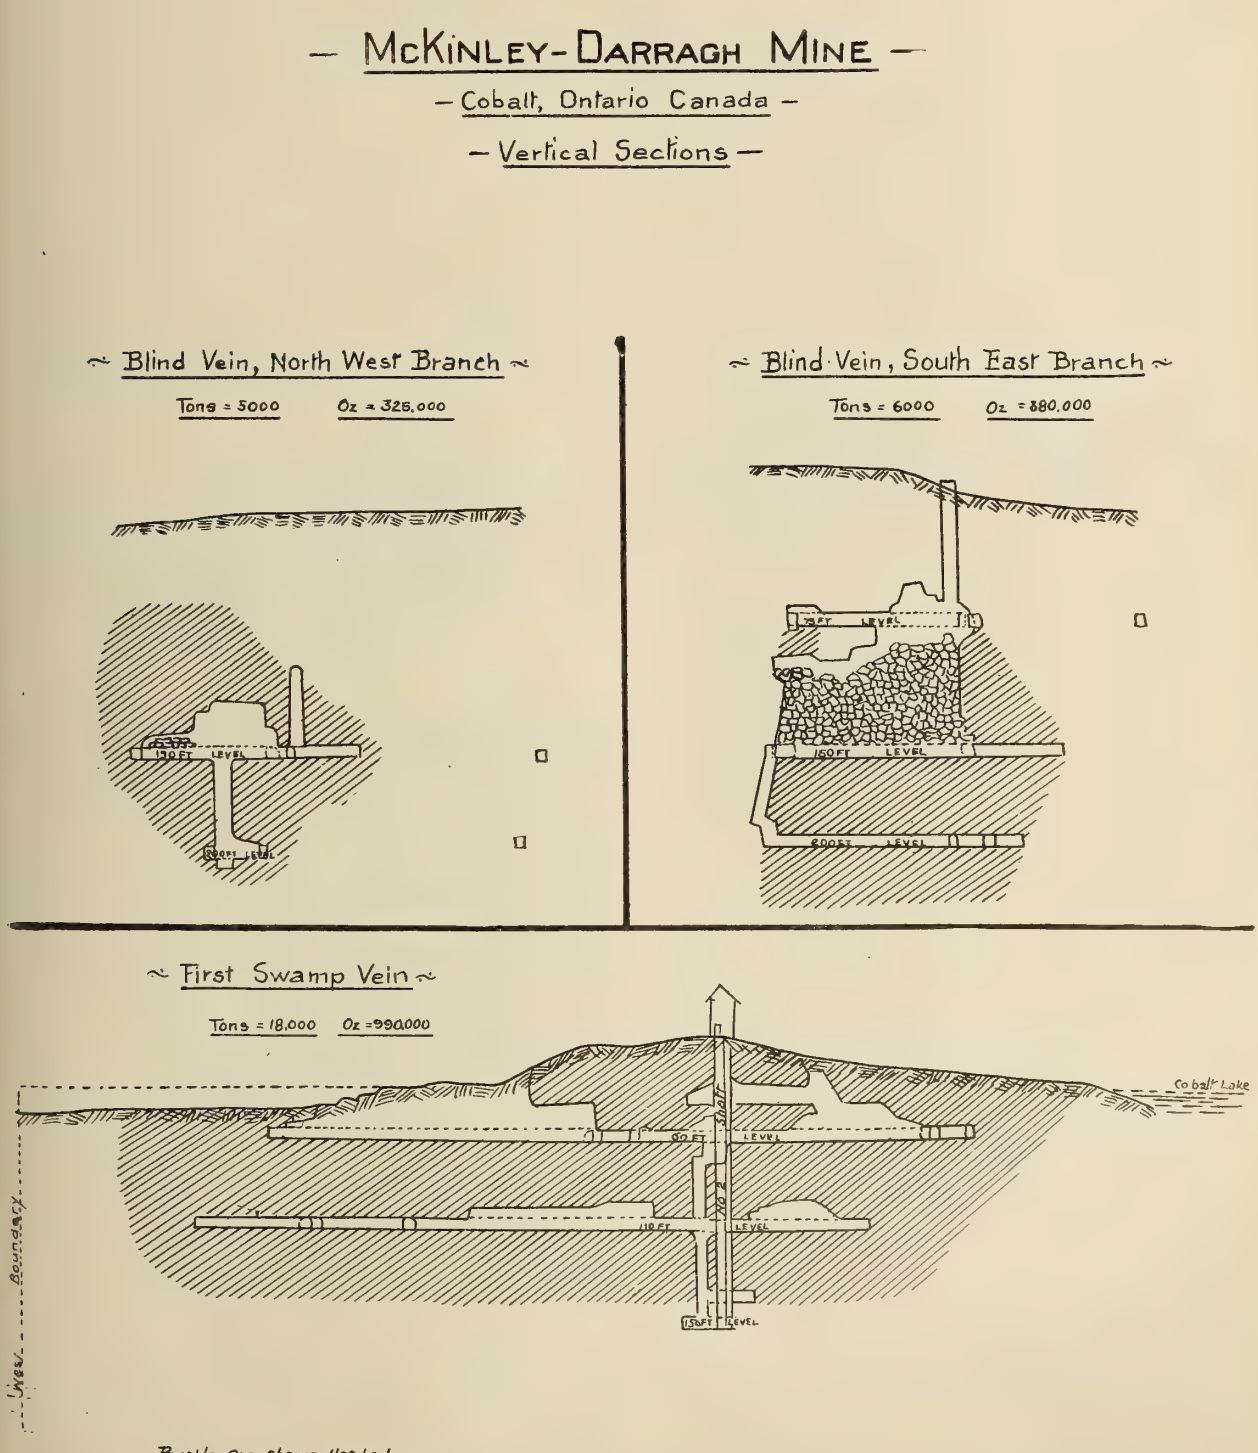
Mining.

We have continued our policy of doing a relatively large amount of crosscutting, and the results, in locating new ore bodies, have demonstrated the value of this method of prospecting.



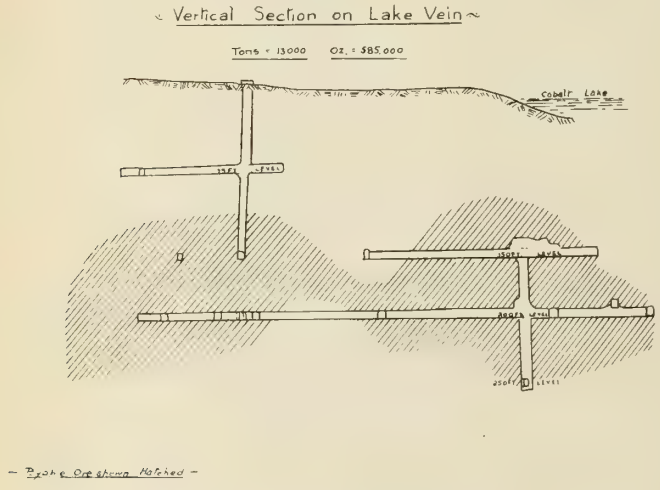
STOPING.—While approximately 3,000 cubic yards of ore have been broken in the stopes during the year, but little over one-half of this has been removed from the mine, the balance being still in the stopes, ready to be drawn off and treated in the mill when required.

At the beginning of the year we had a large amount of ore broken in the mine, awaiting treatment by the mill.

Around our No. 1 Shaft, which is the hoisting shaft, there had accumulated a considerable tonnage of low-grade ore which was also destined for the mill. This broken ore in the mine and on the dumps interfered greatly with our development work, as it had to be removed before good progress could be made.

As you are aware, the No. 1 Shaft is located in a gully, with our discovery vein on the north, power plant on the west, T. & N. O Railway on the south and a hill side on the east, leaving a very constricted area available for waste and ore dumps.

In order to carry on crosscutting it is necessary to have space in which to dump the waste rock, and it



was to provide this space that we milled a quantity of ore which was lying around No. 1 Shaft.

During the year we have overcome these difficulties and provided sufficient waste dump space to carry us through the coming year, so that we shall be able to carry on our mining operations under more favourable conditions.

Accompanying are plans showing the location of veins upon the property, and also sectional elevations showing development, stoping and estimated reserves of the principal ore bodies. Reference to these will guide you in understanding the following remarks:

LAKE VEIN.—Development work consists of 194 feet of drifting on 150-foot level; 480 feet of drifting on 200-foot level; winze from 150 to 250 feet. The vein cut off at 235 feet in the winze, but is almost certain to be picked up again at 250 feet by means of a cross-cut. This vein is in conglomerate and lower Huronian.

Estimated ore reserves and silver contents,
13,000 tons at 45 ozs.=585,000 ozs.

BLIND VEIN.—This vein has been stoped out above the 75-foot level, and considerable stoping has been done between the 150 and 75-foot levels. On the 150-foot level drifting amounts to 545 feet, and on the 200-foot level 320 feet of drifting have been done, and two winzes sunk between 150 and 200 feet. This vein is in conglomerate and lower Huronian.

Estimated ore reserves and silver contents,
22,000 tons at 65 ozs.=1,430,000 ozs.

FIRST SWAMP VEIN.—Drifting 60-foot level, 384 feet; 110-foot level, 445 feet; 135-foot, 28 feet. Raise from 135-foot to 60-foot. Considerable stoping has been done above 60-foot, and a small amount on the 110-foot level. The vein is in conglomerate and slate.

Estimated ore reserves and silver contents,
18,000 tons at 55 ozs.=990,000 ozs.

SECOND SWAMP VEIN.—Drifting 110-foot level, 475 feet; 150-foot level, 390 feet; three raises from 150 to 110-foot, and one raise from 110-foot to surface.

This vein is in conglomerate and slates. A small amount of stoping has been done on the 150 and 110-foot levels.

Estimated ore reserves and silver contents,
20,000 tons at 55 ozs.=1,100,000 ozs.

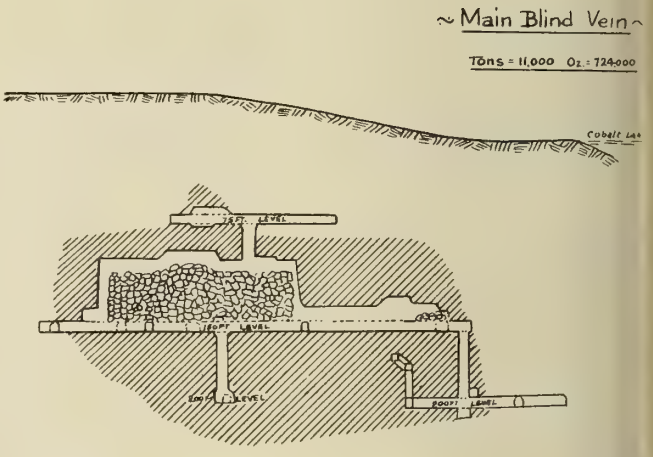
THIRD SWAMP VEIN.—82 feet of drifting on 110-foot level with 30 feet of raise above this level. Good ore in the floor, backs and west face. This vein is in slate, as far as proven.

Estimated ore reserves and silver contents,
3,000 tons at 50 ozs.=150,000 ozs.

The foregoing constitute the ore bodies upon whic the bulk of development work has been done.

Besides these there are:

No. 7 VEIN—stoped out under ground, but still considerable amount of payable ore in open cut sout of shaft.



FOURTH SWAMP VEIN—Trenched on surface 100 fee shaft sunk 20 feet, and vein proved at 75 feet, by work ings of Right of Way Mining Company.

Discovery vein at edge of lake, large tonnage of lo grade ore, and some good high-grade ore in cut, a present under water.

— McKINLEY-DARRAGH MINE —

— Cobalt, Ontario, Canada —

— Vertical Sections —

Northwest stringers from blind vein proved for 12 feet by drifts and crosscuts on 150-foot level, veins a three-quarters of an inch in width, and carry 1,00 ounces per ton.

SOUTHWEST VEIN—80 feet of drifting on 150-foo level in good ore.

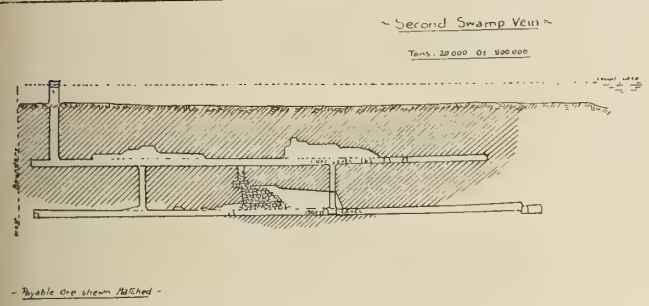
For purposes of including in this report I estimat that these miscellaneous ore bodies will yield 15,00 tons, having a gross value of 30 ounces per ton, givin a total of 450,000 ounces.

Work upon these veins has not been pushed, for th reason that the output from the rest of the mine ha been all that we could handle.

Last year, ore on dumps was estimated at 10,000 ton During 1909 we have milled 3,178 tons of this. Th estimate of last year was too conservative, and we sti have approximately 9,000 tons of milling ore upon th dumps, which will contain 30 ounces per ton, or a gro value of 270,000 ounces.

Recapitulation of Estimates.

Lake Vein	13000 tons at 45 ozs.	585,000 oz
Blind Vein	22000 tons at 65 ozs.	1430,000 oz
1st Swamp	18000 tons at 55 ozs.	990,000 oz
2nd Swamp	20000 tons at 55 ozs.	1100,000 oz
3rd Swamp	3000 tons at 50 ozs.	150,000 oz
Miscellaneous	15000 tons at 30 ozs.	450,000 oz
Dumps	9000 tons at 30 ozs.	270,000 oz
	100000	4975,000 oz



Having made arbitrary allowances for extensions of the ore bodies beyond the limits of our workings as at January 1st, it is obvious that exact figures would be misleading in regard to the accuracy of my estimates, and I have, therefore, used the nearest even thousands, as those figures are more eaily carried in the mind and are sufficiently close to the truth for the purposes of this report.

Referring to the tabulated figures covering ore production for the year, and taking the months since we started milling, the yield per ton has been:—

These results are higher than we can hope to maintain throughout the life of the mine, and in order to place a more definite valuation upon our ore reserves, during the month of December we milled ore which could be taken as more representative of the whole mine, as follows:

1st Swamp Vein, 110-foot level.....	837 tons.
Blind Vein, 150-foot level.....	495 tons.
Southwest Vein, 150-foot level	36 tons.
Lake and Blind Veins, 200-foot level....	534 tons.
	1902 tons.

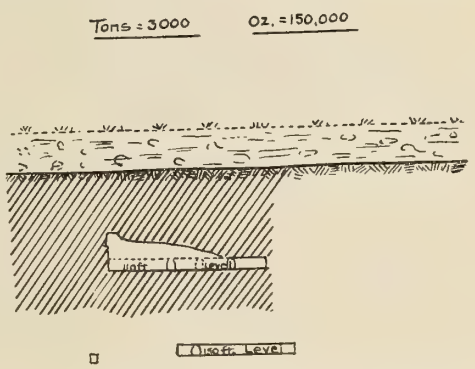
The recovery for the month was 85,284 ounces, or 44.84 ounces per ton, and the average mill tailings carried 6.26 ounces per ton, making a total value per ton of 51.10 ounces.

It is not possible without any extensive development work, and sampling, to accurately gauge the value of the ore reserves, owing to the great variations in values which occur within a few feet. In one case, the Blind Vein, at 75 feet, is about two inches in width and carries 4,500 to 5,000 ounces per ton. There is little silver in the wall rock, and the stopes have to be carried as narrow as possible. At 150 feet the vein is split into smaller veins which carry from 2,000 to 2,500 ounces per ton, and there is considerable value in the wall rock, permitting stoping widths of over ten feet in places. At 200 feet the stringers are more numerous, smaller, carry from 1,500 to 2,000 ounces per ton and the wall rock is not so heavily mineralized as at 150 feet. Like variations occur in the other veins, and it will, therefore, be understood that figures must be approximate, but I believe that those given above are a conservative estimate of our probable ore reserves, as they are based upon some hundreds of samples, and are checked by actual returns from milling.

To estimate the possible ore, as distinguished from the probable ore, is a still more difficult matter.

On the north, Cobalt Lake Mining Company is working two rich veins which run into our property and which appear to be continuations of our 1st and 2nd Swamp Veins. This being so, we could expect an addition of 300 feet to the known lengths of each of these veins. My policy is to leave the 4½ acres, which we own under the lake, until the rest of the mine is worked out, so as to avoid any possibility of flooding our workings.

Near the northwest corner The Right of Way Mining Company is working a vein which is yielding good ore, and which appears to be an extension of our 4th Swamp Vein, upon which we have as yet done no development work.



On our west, the Princess has two veins making toward our property. It is possible that one of these is an extension of our 1st Swamp Vein, which fact would add 100 feet to the length of this vein as developed at present.

Our No. 7 Vein, (an extension of the Kendal Vein of the Nipissing), constitutes another factor in possible ore reserves. There is still some ore to be stoped on the surface, and at 120 feet a strong calcite vein in diabase remains to be explored. During the past year only a small amount of work was done upon No. 7. We have in the southeast portion of the claim, several veins of smaltite, which carry small silver values on the surface. Nothing has been done to prove these at depth.

— McKINLEY-DARRAGH MINE —

— Cobalt, Ontario Canada —

~ Verfical Section on Third Swamp Vein ~

In the western portion of the property we have found by means of crosscutting, seven small silver-bearing veins of calcite and smaltite, upon which no work has been done other than locating them by means of crosscuts; there is always a possibility that some of these will develop into good producers upon further development.

In the matter of depth, we have not carried on any exploratory work below 200 feet. One winze has been sunk on the Lake Vein to 250 feet, but nothing further has been done, as the development work on the upper levels has kept our plant going at full capacity. There are indications that the ore shoots of the Blind and Lake Veins dip to the south, which, if true, will give us ore at still lower levels. This, however, is a matter of conjecture at present.

From the foregoing, it will be evident to you, that while in the matter of estimating probable reserves, we are bound within more or less definite limits, the possibilities of the property may be discounted as having much wider limits, and there is every reason to expect that the life of the mine will be materially increased by the development of some of the factors at present

classed as "possibilities," or by the opening up of new ore bodies at present undiscovered.

Milling.

The new mill was started on February 8th, when ten stamps were put into commission, followed on March 11th by the remaining ten.

Considerable experimenting was required at first before the mill could be worked up to its full capacity, and it was not until May that satisfactory results could be depended upon. Since then there has been a steady increase in tonnage treated, and a corresponding decrease in costs.

The costs for the month of December were unusually high, due to the shutting down of the mill for two days at Christmas in order to make certain repairs, and also due to the laying in of a surplus stock of coal, the costs of handling which were charged into December operations.

During the first month of 1910, we have treated an average of 83.5 tons daily at a cost of $1.48 per ton; a decided improvement over previous performances.

The mill is operated six days per week, which accounts for the comparatively high milling costs when compared with those of other camps.

All coarse crushing and jigging are done in one shift, but the balance of the mill, from the stamps on, is operated 24 hours per day.

Mill Extension.

During the year it became evident that the mine was opening out to such an extent that an increase in milling capacity was desirable, and an extension has been built consisting of ten 1,250-pound stamps, one 8-foot Hardinge pebble mill, twelve shaking tables and a set of canvas tables.

The following tabulation shows more concisely the relation between the original mill and the new extension:

Apparatus.	Number in Original Mill.	Number in Extension.	% Increase in Capacity.	Total Number in Extended Mill.
Jigs	6	..	..	6
Stamps	20	10	50%	30
Sand Tables	4	6	100%	10
Tube Mills	1	1	100%	2
Vanners	4	..	..	4
Slime Tables	8	5 Slime; 1 Sand.	90%	14
Canvas Tables	..	10	..	10

It will be noticed that our stamping capacity has been increased but 50 per cent., while the tables and fine grinding tube mills have been increased 100 per cent. This gives us a better balanced mill, as in the past we have had insufficient tables to treat efficiently all of the product obtainable from the stamps.

The extended mill can treat 140 tons per day, but it is expected that only from 110 to 120 tons daily will be milled. The extension is almost completed and some of the tables are already operating.

Attached "flow sheet," plan and elevation of the mill illustrate the process of concentration in its various details. A photograph of the extended mill is also attached hereto.

So far, it has not been demonstrated that any other process of extraction possesses commercial advantages over straight concentration as practised by us, but there is every hope that the cyanide process will be developed to a point which will insure increased profits from milling.

Within a few weeks we expect to be driving the mill by electricity, developed from water power, a change which will net considerable saving in the cost of power. This saving in power costs, taken with the increased tonnage to be treated, will enable us to reduce milling costs to approximately $1.30 per ton.

A further economy will also be achieved through the installation of canvas tables, making possible a higher extraction of the values, and it is hoped that the values in our tailings will be cut down to between four and five ounces per ton.

(To be Continued.)

THE ELEMENTS OF SLIME CONCENTRATION.

By Walter McDermott.

(Paper read before the Institution of Mining and Metallurgy.)

Introduction.

In considering the progress of concentration methods for the last thirty years, it appears possible to draw certain conclusions, which may be considered as elements governing the probable developments in the future. To those who have been in touch with this branch of ore treatment, it is very evident that there has been nothing revolutionary in the best practice for the period mentioned.

There have been hundreds of inventions; there have been some dozens of commercial introductions of new machines, which were expected to be revolutionary, but which have had only a short period of favour, followed by disappearance from use; and there have been a very few new types which have survived the struggle for existence. The most striking fact has been the very wide and increasing use of two types of machines, the shaking belt and the jerking table.

Inventors, of course, will invent, and they will hope; but very often they will not investigate what has been already done; and those persons who have been in the position to hear of and examine many new inventions, must be continually struck with the fact of the recurrence of exploded ideas, and the existence of certain limitations which must be considered in a successful slime saver.

It is easy enough to save the coarser particles of any mineral with a specific gravity admitting it into the concentration class, so that invention is more prolific in the means of saving the finest particles. Experience all over the world, on all kinds of ore, has certainly demonstrated a number of facts which enable one to decide pretty accurately the chances of success for any new invention by a mere examination of the principle on which it works, and of its details of construction, without any actual trial on a given ore. Many think that every new invention must be tried before it is judged.

Even on actual new inventions this is only partially true; because life is too short and capital too limited for trial always to precede judgment; but in the vast majority of inventions the novelty is only a novelty to the inventor: the machine itself is an immaterial modification of something already tried and condemned, or it is opposed in principle to established conditions of success.

The following notes are an attempt to put down certain elements which to the writer seem established by practice; and to draw certain conclusions which may be of service as indicating the most promising direction for improvements in the arrangement of old machines, or in the designing of new ones.

Definitions.

Although the chief subject matter of these notes is the discovery of slime mineral, some of the processes to be discussed cover a wider range of sizes than what are usually understood by the term "slime," and a number of machines are in present use which deal at one operation with this wider range. To restrict the field of discussion it is proposed to confine this paper to the treatment of material which has passed a screen equivalent to 40-mesh I.M.M. standard, that is, apertures of .0125 inch.

As the functions and efficiencies of a number of well-known machines are to be referred to, it is desirable to point out that to-day there are practically no master patents in existence on the best known types of machines; that these types are all (with varying details) manufactured by a number of firms; and, therefore, it is possible to refer broadly to types of machines without being misunderstood as referring to makes of machines. The following classification is herein adopted as covering all the machines necessary to refer to for the purposes of this paper:—

1. Fixed inclined tables (including slowly travelling tables).
2. Jerking tables (including bumping tables).
3. Shaking travelling belts.
4. Jerking or bumping travelling belts.
5. Shaking side-inclined belts or tables.

Class I.—"Fixed Tables" are illustrated by various forms of frames, with wood, canvas, blanket or other surface; by the old Cornish buddle; and by various forms of revolving buddles and side-inclined non-shaking belts. The slow revolution of a buddle or belt, and the intermittent automatic discharge of a Frame, do not affect the actual operation of concentration on the surface, so all are included in the class of fixed tables for the sake of simplicity and brevity.

In this class, all the machines depend for results simply on the greater resistance of the specifically heavy minerals to the wash of water down an inclined surface, as compared with the resistance of the lighter waste. The more perfect of these machines do not make a simple division between "Concentrate" and "Tailing," but they have to make an intermediate or "middle" product in order to yield a clean concentrate.

Class II.—"Jerking Tables."—This class depends for results on a combination of greater movement across a table, and greater resistance to wash of water down the table, of the specifically heavy particles, as compared with the motion and resistance of the lighter waste particles. For high efficiency this class, like Class I., must produce a middle product; because, in most cases, a hard line of division between Concentrate and Tailing is not possible.

Class III.—"Shaking Belts."—The operation of this class depends on a greater variety of conditions than need be considered in the preceding two classes; and a misunderstanding of these conditions has led frequently to hasty generalizations as to the requirements for most useful efficiency.

The shaking or vanning motion not only settles the heavy mineral on to the travelling surface of the belt, but it prevents the larger particles from clinging to the surface. The upward travel of the belt is in opposition to the flow of water; it tends to keep a bed of the coarser particles on the belt, and this bed checks the too-rapid flow of slime material down the incline. The shaking motion, by keeping the bed from packing on the belt, allows of much less inclination on this than on a Fixed Table, therefore of less rapid current of water. This class makes no middle product, which fact is a limitation on some ores, but a great advantage on others, where only one class of Concentrate is required.

Class IV.—"Jerking Belts."—The actual concentrating process on this is the same as in Class II., but it is carried out on a side-inclined travelling belt, going in the direction of the "throw" of the concentrate, and so the discharge is assisted and does not depend entirely on the "throw." This class makes a middle product also. In some modifications, owing to the nature and frequency of the jerking or bumping motion, a complication is introduced in the relative conditions as the settling motion approaches one of the conditions in Class III. machines and has less of the jerking action so important in Class II. machines. Such modification merges then into Class V.

Class V.—"Shaking side-inclined Belts or Tables."—This type of machine is not much employed at present, though it has been re-invented a number of times in different forms. A slowly revolving buddle with a shaking or bumping motion works in effect the same way as a side-inclined belt. The shaking motion yields some of the advantages of Class III. by assisting the settling of the slime material, diminishing the inclination of bed and lessening the water required on fixed surface machines; but a middle product is produced; and the longer settling surface and thickening effect of the upward travel of the belt in Class III. is not obtained.

Conditions Affecting Efficiency.

To understand the conditions necessary for a close saving of fine mineral, it is advisable to begin by examining the action of the simplest (and at the same time the most perfect) appliance in use; and this is the vanning shovel, or some equivalent tool, in the hands of an experienced man. The quantity of material operated on is small; time is of no object; and the action of the tool can be varied to meet the requirements of the moment; so that all the conditions are in favour of the most perfect work.

For proper work, the shovel surface must be smooth; and it must be of a very slightly curved section in all directions. There are two distinct systems used with the shovel: the one for throwing up mineral which is not exceedingly fine, and the other system for separating the finest sizes of mineral from the waste. The first employs a motion which is in effect the action of the jerking machines of Classes II. and IV. The second movement (used for the slime mineral) is the washing back of the waste by a succession of waves of water from the fine mineral—previously settled on to the shovel surface, by a shaking motion. This second separation is in effect, but in varying degrees, the action of Classes I., III., and V. machines.

Passing by the question of the saving of the coarser particles of mineral, as being unimportant for the purposes of this paper, the second motion of the shovel may be further explained. To take it in its most refined work, it can be assumed that a sample of tailing, from a concentrator working only on slime, is under examination in order to see how much fine mineral is escaping. The shovel, having its charge of sample (as flowing from the concentrator) is nearly full of water, with fine waste and fine mineral in suspension. No separation of waste and mineral can be at once made; but the first operation is to settle all the solid matter possible on to the surface of the shovel. This settling is assisted by a circular steady shake of the shovel, which shake at the same time works down the heavier material, however fine, into actual contact with the surface, and below the lighter waste. A rapid shake assists in concentrating the settled mineral at one spot. When the elements of settling time, and settling motion have sufficiently operated, a series of slower and wider sweeps of the shovel introduces the separating effect of gentle waves of the water, which gradually move the lighter waste along the shovel, and leave exposed the "head" of fine heavy mineral. In this final separating movement there is a combination of the shaking with the washing action, as facilitating the movement of the lighter waste over the surface of the shovel.

The perfect work of the vanning shovel is shown by the fact that it will always give, from the most perfect commercial concentrator, a definite head of the fine mineral which is going to waste. This perfection of work of the shovel being established, its conditions of working may be taken safely as a guide to the conditions necessary for close slime concentration in practice; and conversely, it can be accepted that machines which ignore the conditions essential to good work by hand vanning give only very imperfect results in the saving of slime mineral.

The conditions which are essential to good work, irrespective of the skill of the operator, can be stated as follows:—

(A) Sufficient time for settling.
(B) A smooth surface for final separation.
(C) A gentle movement of the washing water.
(D) A motion to assist in differential settling and in separation.

These elements deserve detailed examination as to their application to the construction and operation of concentrators of various kinds.

(A) Time.—It is quite evident, if a very small sample on a shovel must be given a relatively long time to settle before any separation can be effected, that no machine will do close work on slime mineral unless the fine particles are given adequate time to settle from the water in which they are suspended.

As all commercial machines are continuous in operation, this function of settling time becomes in effect the ratio of quantity fed to surface and rate of flow. It follows conclusively, that if a new machine is produced for which a large capacity is claimed, while the settling surface is relatively small, no arguments based on motion or principles of construction will meet the immediate criticism that an essential element of success has been ignored by the inventor.

It is true that there is a point of difference between a continuous flow of pulp over the surface of a commercial machine, and the settlement of solid particles from a nearly stationary charge on a shovel. This difference lies in the fact, that a thin layer of pulp slowly flowing down an inclined machine surface will, by mere frictional contact of some of the particles with the surface, deposit such particles. This fact, however, does not affect the general truth of the proposition that feed must be adjusted to settling surface and speed of flow, so as to secure the element of settling time.

(B) Smooth Surface.—What is well-known to be an essential for satisfactory hand vanning—that is a smooth surface—has been proved by general experience in the use of concentrators for slime mineral to be also best in commercial work.

It is true that canvas tables and blankets are used under certain circumstances; but such surfaces cannot be considered in the list of perfected concentrators; they are either used for special purpose (as in the case of blankets for the saving of fine gold) or as supplementary catchers of a little valuable mineral from the tailings of more perfect machines. It is a constantly

recurring fallacy that a rough surface must be good for saving slime mineral. The fact that it is also good —and in fact relatively better—for saving fine waste, quite annuls the supposed benefit of its retaining power on the mineral. If a clean concentrate is required the current of washing water must be so great, to prevent the waste clinging, as to involve loss of fine mineral; and if clean concentrates are not required, the machine is not a concentrator: it is only a contrivance, like a settling pit.

The history of past practice and an inspection of the most successful working of the present day, show that the advantage of a smooth surface is generally recognized. Tables, buddles and belts have been made of wood, glass, slate, marble, cement, rubber, etc., all with a view to getting the necessary degree of smoothness.

The extraordinary clinging power of very finely-divided mineral, when once settled on to a smooth surface, is seen in the action of any of the machines of Classes I., III. and V., when an excess of wash water is turned on; for the lighter waste and the larger particles of mineral are driven off long before the finest mineral can be moved from the surface it has adhered to. To free a smooth vanning shovel from fine mineral after a test, it has to be immersed again and again in water, or put under a strong stream. The possibilities of rough surfaces, varying all the way from coarse riffles in a launder to a smooth close canvas, have been exhausted long ago; and therefore a new concentrator, for which some form of rough surface is claimed as the chief advantage, can be safely left for time to dispose of.

The action of stratification within definite cavities by a shaking motion, is quite different from the mere arresting effect of a rough surface above referred to.

(C) SPEED OF WATER.—The bad effect of an excessive rate of flow of water over a concentrator surface is two-fold. A rapid current is, of course, in the first place, unfavourable to the settling of fine mineral; and, in the second place, it is apt to re-float and carry off some of the particles which by rolling contact with the surface of the concentrator have succeeded in settling.

It is elementary that a too great inclination of a concentrator and an excess of water are both unfavourable to close work. It is unnecessary, therefore, to illustrate the effects of these conditions, combined under the head of "speed of water;" but the importance of the point is sometimes overlooked in the comparison of certain types of machines for certain work, and in the designing of new machines for obtaining large capacity.

(D) SETTLING AND SEPARATING MOTION.—It is difficult to explain to those unused to hand vanning, how important is the shaking motion imparted, and in how many varying ways it can be used, guided by the eye according to how the mineral and waste are settling and distributing over the surface of the shovel. The whole success of the operation, and the clear exhibition of the "head" of fine mineral separate from the body of the lighter waste, depend on the way the settling is accomplished, and on the way gentle washing waves of the water are made to travel. A proper motion keeps the lighter waste in semi-suspension in the water, free to move over the clinging, sluggish mineral particles; whereas if both waste and mineral are allowed once to settle fully on the shovel (to pack) the waste cannot be moved except by such a strong wave of motion as is certain to pick up and move much of the fine mineral also.

In considering the effect of the shaking motion in actual concentrators in practice, it will suffice to take a machine of the shaking belt class, and note the effect of stopping the shake. The machine becomes at once of the Class I. type; it is a self-discharging Frame. Its inclination must be increased, or water supply made much larger; its loss of fine mineral will be much greater, and its concentrates will be less clean than when running in its normal way on the same feed of material.

Another very important effect of the shaking motion is that unclassified material can be treated in a way not otherwise possible, both on the shovel and on shaking belt machines; and this will be referred to more fully below in treating of classification.

Direction of Probable Improvements.

If the above evidence and conclusions are accepted, it is perfectly justifiable to judge any proposed new concentrator by its agreement with, or departure from, certain principles. The design will doubtless fall within one or other of the five classes described above; unless it falls into one or other group of certain well-travelled and exhausted lines, such as rate of settling in water; resistance to upward flow of water; centrifugal separation; separation by air; separation in a denser medium than water; and flotation processes.

Putting aside the last-named group (flotation processes) as not really in the nature of concentration by specific gravity, and so not within the limits of this paper, it is worth while pointing out one of the great obstacles to the perfection of a machine for saving fine mineral by any of the other principles just mentioned.

No system of practical classification has yet been invented which does not in the end leave a great difference in the sizes of particles contained in the final class, the class in which the great loss occurs in concentration. As a consequence, separation by rate of settling, by upward flow of water, by a denser medium than water, all become imperfect and are usually quite impracticable.

It is well known that air separation—already tried in dozens of different ways—is most satisfactory on dust, and it is usually inapplicable for commercial reasons.

Many have been the attempts to employ centrifugal force, which on first thought seems eminently adapted to the saving of fine particles by its power of intensifying the function of specific gravity, but in practice its application becomes impracticable. With such fine and unequally-sized particles as are under discussion, a separation by mere form of trajectory is not possible; and, as a consequence, the action of a centrifugal concentrator must be almost necessarily one of packing the material against the sides of the revolving machine. This action of packing, or building up on the walls, is in its very nature absolutely opposed to any continued separation of particles of differing specific gravities when once fairly started; and hundreds of failures witness to the apparently insuperable difficulties of making a continuous discharge to this class of machine. Attempts which have been made to combine a washing separation by water (requiring a freedom of motion between particles) with the packing action of centrifugal force, seem to point to an inherent antagonism between the two forces which would require a delicacy of adjustment impracticable in practice.

From the above, it seems probable that new concentrators which require serious consideration will be modifications of established types; and to meet the expectation of doing work comparable with that of exist-

ing machines, they can pretty safely be judged by the extent to which they meet the conditions which have been referred to. Of course, all new machines are said to do wonderful work; but history shows how exceedingly difficult it is to get at comparable facts, and how very unreliable as a guide are the testimonials and figures of millmen in the matter of concentration. The great variety of practice all over the world, even on similar ores, in both the use and distribution of different types of machines, shows at once how difficult it is in this branch of milling to get rid of the personal element, and the limiting effect of special experience; and again, the influence of mere fashion is often apparent in the arrangement of mills.

It may be mentioned here that on ores from which a single concentrate is required (not, for instance, concentrates separate of galena and zinc blende from waste) it is not advisable to make a middle product. A middle product may be needed when the coarsest particles carry attached mineral and need regrinding; but on material finer than 40-mesh this is not often the case. Many concentrators do make middle products; and it is certain that losses are incurred, and are often obscured, by the fact that the middle product must be re-dressed; for a secondary loss is thus involved, and must be added to the loss in the Tailing of the first operation.

There are often good reasons in practice for using a middle product-making machine; but it should not be overlooked that, in principle, and for the conditions assumed, there is a definite objection to the system; and, therefore, in designing improvements over existing machines, it is a point which will count in actual commercial results in the end. Questions of capacity, cost, and expediency often influence the choice of the details of arrangement of mills; but the question under discussion is one of individual efficiency of work, which should be well weighed in the first instance. It is known that in modern concentration mill losses are often high; it is, therefore, no heresy to refer in detail to certain probable causes of loss in existing practice.

To sum up the conditions which seem from the above to be most favourable to the evolution of any new concentrator which may reasonably be expected to prove an advance over existing machines, it can be said that there must be a large and smooth surface; a regular settling motion which does not jar the finest particles from their contact with the surface when settled; and a delivery of clean mineral without the production of a middle class. The provision of a proper settling motion insures the other necessary conditions of slight inclination of surface, and the minimum quantity of water in pulp and for washing purposes. For example: a revolving buddle, which as ordinarily used, will require an inclination on its surface of 1½ inches to the foot, can, with a proper shaking motion, work to better advantage with ½-inch fall, and will need less water.

Classification.

The necessity for classification before concentration is so marked in some cases and with some machines, that it is accepted by some people as a comprehensive dogma with full scientific warrant; but actual experience has shown very clearly, that in certain cases it is distinctly undesirable, and in other cases it is so imperfectly applied as to largely neutralize its advantages.

Bearing in mind the limitation in this paper to the consideration of material finer than 40-mesh, it is a clearly-demonstrated fact that machines of Class III. (shaking travelling belts) give better results both industrially and theoretically without classification. At intervals of some few years new teachers arise to point out that the treatment of an unclassified pulp is in contravention of elementary laws of scientific concentration on any machine. It will be worth while here to push this argument to a conclusion: to see what, if anything, science has determined, and what practice has demonstrated.

In what scientific formula has it ever been attempted to lay down the relative values of the functions of specific gravity, inertia, surface resistance, speed of settling, friction of grains, rate of water flow, and adhesion to machine surface, in the case of a mixture of particles from 40-mesh aperture to impalpable slime, on a machine of Class III. type?

Such a formula might amuse a mathematician; it would be beyond the comprehension of the writer and of most people; and it would carry no conviction whatever in a practical sense. It is only necessary to fall back on certain results and details of actual operation, to show that some of the functions above named are so different relatively on different types of machines, as to make conclusions draw from one machine inapplicable to the results to be expected from another machine. An illustration will help to make this clear. If a silver or copper coin be put on a machine of either I., II. or IV. Class it will be delivered with the concentrate. If the coin be put on a machine of Class III. it will not be delivered with the concentrate. Any scientific formula which correctly accounted for these opposed results could never be construed into a dogma sification has led to some curious results. A very un- on classification in general, since the effect of the function of inertia is quite different in the two cases.

It is known that classification is not necessary for a sample treated on the vanning shovel; and as this treatment is taken above as a standard of work, and as a guide to investigation, it would seem to indicate in advance that classification is not a fixed law of perfection in concentration.

Furthermore, the experience of thirty years, on all kinds of ores, in many different mining fields, has established most definitely the fact that there is a distinct advantage in treating unclassified pulp on machines of Class III. The coarser particles form a bed on the belt owing to its upward travel; and the fine slime instead of flowing down in unchecked waves over the belt surface (as it would do if treated alone) flows more slowly, by a filtering process in part, and so has better chances for settlement of the fine mineral.

In practice, the blind adherence to the belief in classatisfactory method of classification is usually adopted, that of simple pointed boxes. By this system the coarser or bottom discharge is of necessity accompanied by a stream of the finest slime; and this last goes to a class of machine not adopted to its treatment. In some modern mills, arranged specially with a view of keeping coarse and fine apart for separate treatment, the first step, that of classification, is thus most imperfect. A step in advance is made in some cases by the introduction of upward flow classifiers, with a disadvantage from the continued dilution of the stream of pulp for the final treatment. The experience obtained in some of these mills has led to the supposed discovery that machines of Class III. are not proper machines for slime treatment, and they are, therefore, given an intermediate product of the classification system.

This conclusion is quite opposed to general experi-

ence; because machines of Class III. were originally developed for, and are continuously used for, the direct treatment of ores crushed fine in batteries, and containing small quantities of finely-divided and brittle minerals, which are valuable enough to demand very close saving. Such ores, crushed under such conditions, must need close saving of slimes, and must make much slime value, and it would be a remarkable thing if a class of machine which is so successfully used for such work should be now discovered to be not adapted to slime saving. The explanation of this erroneous conclusion is simple, namely, that by attempting classification ,and then experimenting with the very diluted slime alone, the machines of Class III. are not working under the best conditions; and they have, furthermore, very little capacity when so improperly limited as to size of pulp, and when so overcharged with water.

In most of the large modern mills of the United States and Mexico, machines of Class III. are used for the finest sizes, and the slime losses due to imperfect classification already referred to, are sometimes diminished by a re-treatment of the Tailings of Class II. machines on machines of Class III. In some of these mills the finest overflows of classifiers or thickening boxes are run into settling pits, and treated as a concentrate for addition to richer products for the smelter; but such treatment is not available when clean products are essential to subsequent treatment, for example, with ores. Of late there has been a tendency to the use of fine screens in place of some of the water classifiers in a mill, to this extent avoiding the slime discharge of the ordinary classifier with the coarser particles, while making a separation by size alone, instead of by equal falling particles.

It is a very usual thing in mills to treat the tailing of one slime machine by another machine of the same or different construction; for example: buddles are often made double; or a convex surface may be followed by a concave one; and frames or canvas tables may be used in a long succession, each saving a little. This double treatment can be used with great effect on machines of Class III. treating unclassified pulp, but is very seldom attempted. The loss in the tailing of the first machine is in part saved by the second, and in some cases (for instance, with tin ores) where the pulp from the stamps is fine enough to go direct and unclassified to the first machine, the double treatment will be most effective as compared with a classification and treatment on several types of middle product machines. To get the best results from the second machine, it is advisable to use a large pointed box between, to get rid of some excess of water introduced by the first machine; and an increase in belt surface on the second row will add to the efficiency. By this system the slime mineral has a double chance of being saved; there is no excessive dilution of the slime; clean concentrates can be produced; the losses due to rehandling of middle products are avoided; and the whole plant is the most simple and automatic in character. If the tailing of the second row of Class III. machines contains enough fine mineral to be worth additional treatment, a properly-arranged classifier will deliver this mineral in the fine overflow and in a condition suitable for treatment on revolving buddles or frames, or other wide surface appliances suitable for poor material.

When a screen is used in the battery too coarse for effective work by machines of Class III., an additional finer screen can be used to take out one or more sizes of particles for machines of Class II., or even for jigs.

Note.—The use of the vanning shovel is not very general, outside Cornwall, and most enquirers will find it easier to use a circular placque of white enamelled iron, or of china. Such a placque has the additional advantage of retaining a good, clean, smooth surface, and of showing up more clearly the "head" of most minerals, than a shovel.

OUR EUROPEAN LETTER.

LONDON'S MINING MARKET OVERSHADOWED BY THE RUBBER AND OIL BOOM. A FEW FACTS ABOUT THE RISING OIL MANIA. THE RUSH OF NEW MAIKOP COMPANIES. TWO WARNINGS. GERMAN INTEREST IN THE RAND. GOLD MINING IN FRANCE. THE SURFACE CONDENSER IN MINING POWER PLANT. RESCUE APPARATUS. PEACE IN THE BRITISH COAL-FIELDS.

Exclusive correspondence of Canadian Mining Journal

London, April 20th, 1910.

The rise of the rubber boom with the temporary extinction, to all intents and purposes therefore, of interest in other sections of the Stock Exchange (the mining ones included) looks like being followed by an oil boom. Of course, no one expects this to be nearly so big an affair as the rubber mania has become, but tremendous profits are being made by speculators already.

The speculation largely centres in shares of companies in the Maikop district, on the Black Sea, concerning the potentialities of which shares many favourable reports are being received. Most of the companies have been formed since the great "spout" occurred last September and ground is not now cheap to acquire in the oil district.

Russian oil, hitherto, has been drawn almost wholly from the Baku district. At one time in the history of the older field the bulk of the oil was consumed as fuel, its distillation for lighter oils being disregarded. There can be little doubt that it was due to English enterprise that Russian burning oils have been so largely imported into this country and a new department of the industry built up.

The new Maikop fields are looked to for the revival of the waning glories of the past. Should surface indications be justified, Maikop will have a brilliant future undoubtedly, not only from the point of view of actual production, but in its effects on the oil fuel question and the world's demand for additional supplies of illuminating oil. Russia has been, with the United States, the world's principal oil provider, but recently its condition had been giving rise to considerable disquiet and a second Baku has come along in good time. About twenty new oil companies have already been formed this year, and every week now two or three newcomers located in Maikop are being put before the British in-

vestor. As I write, nine new oil companies are announced for issue to-morrow.

As far away and as unknown to the ordinary Englishman as Maikop is, it has apparently already been found necessary to issue a warning as to titles and their validity. It is urged that care should be taken that on conducting agreements for purchases of claims in Maikop, original certificates issued by the Ekaterinodar District Department must be produced, certified copies being useless. Cases are reported from the oil field where people have sold their claims twice over, and having taken so well, no doubt some people will be quite prepared to sell them, on alleged certified copies, another half-a-dozen times each. It has been discovered that a number of Maikop claims now being offered in the London market, do not belong to Cossacks at all, but to so-called settlers. Such claims are declared by Verbitscheff, a leading Ekaterinodar legal authority, to be valueless.

Another thing to be remembered by the British investor in oil shares is that in spite of many romantic ideas to the contrary, oil is not a get-rich business. Immense sums of capital have to be expended on the preliminary borings and the ultimate workings, and a patient historical retrospect shows that hundreds of millions of dollars have been spent on the industry at various times without producing anything like a satisfactory return.

Perhaps the actual incident more than any other which started off the active price of oil shares of all kinds in the market here, was the publication of oil contracts given out by the Admiralty in the middle of February, a circumstance which is taken to mark the beginning of the adoption of oil as fuel in the Navy on a large scale. Efforts have been made for years past to impress the Admiralty with the utility of oil for the generation of steam power, and at last the Admiralty moved.

In the market for South African mining shares, despite competing influences, there has been fair business passing, and a curious side of this is the participation of German investors in this revival. A quick rise recently was followed by a halt, and wisely enough there was no disposition shown to rush in to buy upon the temporary reaction. This cautious attitude must contribute to solidify the basis of what is undoubtedly a carefully-planned "bull" campaign.

The view that the Rand industry is on the eve of a further period of steady progress is, however, rapidly gaining ground. Disinterested cablegrams from Johannesburg reflect also the confidence of those on the spot, and the optimistic feeling which is thus created facilitates the arrangement of "deals" between the leading finance houses and Stock Exchange circles.

According to views expressed by some of the most prominent bankers in London, Germany is displaying a keener interest in Rand affairs than at any time during the present movement. The various large amalgamation schemes which are now formulated, especially the advantages of working on a large scale with centralized management, appeal particularly to the German mind. A large turnover at a moderate, but satisfactory, margin of profit spread over a long period of years, removes mining propositions on the Rand from the speculative side to that of steady industrial working. Patience and well-regulated energy are required, but these essentials played also a prominent part in the growth of Germany's well-ordered home industries. The parallel is sufficiently close to explain German investment buying of Rand shares, and the determinatio of these buyers to wait and back their opinions unin fluenced either by moderate market fluctuations o minor changes in the industrial position.

For a long time people were incredulous with regar to gold mining in France, but now it appears that ther are five mines in active operation and a large amoun of prospecting is going on to find new mines. For th development and equipment of these money will b forthcoming on a liberal scale, and makers of minin machinery should not overlook this. The titles of th five gold mines at present working, are as follows:— Mine de la Lucette, Mayenne; Mine de la Bellière Maine-et-Loire; Mines du Châtelet, Creuse; Mines d Salsigne, Aude; Mines de Villaniere, Aude. The firs mine produces antimonial ore. La Lucette, La Bellièr and La Châtelet are the most advanced in develop ments. La Bellière employs 70 stamps, crushing som 300 tons of ore daily for a yield of 9 hundredweight of gold per ton at a profit of $400,000 in 1909, the pro duction now being over 4,000 ounces monthly. Over 9 per cent. of the gold is extracted.

Several tube mills have recently been ordered, whic are expected to be at work by the end of the curren year. One shaft is down over 300 feet in depth. The Mines du Châtelet treat arsenical ore by Merton fur naces, tube mills and filter presses. At Bonnae the de posits increase in value in depth. Wolfram has beer found in this ore. The mining districts are situated in Central France.

Speaking before the Institution of Mining and Metal lurgy, W. A. MacLeod dealt with the question of the Surface Condenser in Mining Power Plant. During the last two years, he said, he had searched such engineering literature as was available to him with the object of obtaining information on the subject of intermittent condensation. The result had been somewhat disappointing, though he gathered, more by the way of inference than from direct statement, that condensation had been applied to winding engines in some places, but that the consensus of opinion seemed to be against the practice . He had had the opportunity of conducting tests on an intermittent plant of considerable capacity under ordinary running conditions, and had collected a considerable amount of information; and he thought that this, with a study of some aspects of the problem of particular interest to mining engineers, might stimulate a free exchange of views to the general benefit of the mining industry.

Though much of his work was, he realized, incomplete and demanded further and more accurate experimental investigation, yet the results he had obtained did not confirm the somewhat vague adverse stand that appeared to be taken by some engineers against the practice of intermittent condensation. On that account therefore, he thought that a full consideration of the problem might lead to a clear understanding of its merits or defects from an economic point of view. In the rest of his paper, which was of an elaborate character, he discussed first the principles of design, as applied to the similar problem of what might be called "constant" condensation. Having defined the various factors of this problem and their relations to one another, he examined the variations introduced by the "intermittent" conditions, and then considered the altered relations of the various factors under the new conditions, which in ordinary mining practice were "constant" plus "intermittent;" that was, certain machines, such as the air compressors, were running con-

tinuously with an approximately constant consumption of steam, whilst others, as, for instance, the winding engine, ran intermittently, the intermittent periods being brief and frequent, causing sudden demands on the steam, and at the same time on the condenser.

An exhibition of mining rescue apparatus was recently held in the Mining Department of the Birmingham University, Bournbrook. The inventions shown included the "Meco Shamrock" apparatus, which was exhibited by the Mining Engineering Company, of Sheffield; the Draeger apparatus; the "Aerolith," in which liquid air is used; and the Fleuss, Davis, and Hill patents, shown by Messrs. Siebe, Gorman and Company. Most of the firms also exhibited pure air supply tubes and pumps which can be used by men engaged in extinguishing local or "gob" fires in mines, or entering places where the atmosphere is foul. Some of these arrangements were combined with a speaking tube and telephone. Oxygen reviving appliances for restoring persons suffering from the inhalation of poisonous gases were also shown, as well as stretchers and litters, and other first-aid requisites. The exhibition was held under the auspices of the coal-owners' associations of the Midlands. The members of the Rescue Stations Committee inspected the various appliances and witnessed demonstrations of their value.

The exhibition may be regarded as the first step towards organizing rescue stations and brigades to serve the South Midland coalfields. The matter was first brought to the attention of Midland coal-owners by the recommendations of the Royal Commission on Accidents in Mines, and the result was the formation of a general committee representative of the South Midland coal-owners. An Experiment Committee, which they appointed, is requested to examine various forms of apparatus with a view to the recommendation of one or more for use, and further, to embody in a report to the General Committee such suggestions as may enable that committee to formulate a scheme for the establishment of a station or stations for the storage of apparatus and for the training of men in its use.

After having been on the verge of a Titanic struggle the coal miners of South Wales have arrived at an agreement with their employers, although there is still strong resentment against the three-shift system. The matters at variance will now be dealt with by the new conciliation board to be formed under the new agreement, the old one having expired. This dispute has been continuous ever since the Mines Eight Hours Act came into force at the beginning of July last year.

On the Durham and Northumberland coalfields the Eight Hours Act was not introduced until the 1st of January this year, and at once provoked trouble. The miners' union officials, however, arrived at an agreement with the colliery owners and, although a section of the coal miners at first kicked against the official arrangements and several local strikes broke out, peace has now been restored. It is very clear, however, that taking the whole of the coal-mining districts there is a vast amount of discontent simmering beneath the surface, and if the men are not tightly held down by penalty clauses, there may be an outbreak at any time. This will be disastrous to the industries of the whole country.

Inspection of mines in this country at last looks like being put upon a sound footing and both the coal and metal mines are to come under the control of the reorganized government inspection staff. The recommendations of the Royal Commission on Mines are to be adopted. In addition to the existing inspectors and assistant inspectors of mines a superior grade is to be instituted to have charge of each new district, the old territorial classification having been abolished. These officials will be styled divisional inspectors. The general scheme foreshadowed is good, although many people hold that our inspection system, especially as regards safety in coal mines, is already good, despite the fact that some of the lines of progress foreshadowed earlier have not been followed.

KOPPERS' BY-PRODUCT COKE OVENS AT BIRMINGHAM, ALABAMA.

Two hundred and eighty Koppers' By-Product Coke Ovens have been contracted for by the Tennessee Coal, Iron & Railroad Company for its Birmingham, Alabama plant. These ovens will be 37 feet long between doors, 9 feet 10 3-8 inches high, and will have an average width of 19 3-4 inches. Each oven will produce 11.25 tons of coke every 24 hours. With a coal containing 30 per cent. of volatile matter, the daily output of the plant will be 3,145 tons of coke besides 22,000,000 cubic feet of 500 B.T.U. gas, 35,000 gallons of tar and 44 tons of sulphate of ammonia. The ammonia will be recovered from the gas by the Koppers' direct process.

With this plant of 280 ovens, the United States Steel Corporation will have a total of 1,120 Koppers' By-Product Coke Ovens. The first ovens of this type erected in America, were built in 1907 by the Illinois Steel Company at Joliet, Illinois. They have been in operation for nineteen months to date, and they are giving results superior to any previously obtained anywhere in the world, in the by-product coke oven industry.

This is the same type of by-product coke ovens that is being erected by H. Koppers for the Lake Superior Iron & Steel Company, at Sault Ste. Marie, Ontario.

J. H. Haynes, in the April number of the Western Chemist and Metallurgist, gives the cost statements of a concrete battery foundation, built for the Tanguay M. & M. Company, at Idaho Springs, Colo. The foundation base is 16 feet by 5 feet; height, 8 feet; top, 12 feet by 2 feet 4 inches. It contains 12.5 per cent. of rock. It supports ten 1,000-pound stamps dropping five inches, 108 drops per minute. A piece of ⅛-inch rubber packing is inserted between the mortar and the foundation. The cost was as follows:

Labour, excavating	$32.30
Labour, foundation	68.30
Bolts and castings	50.00
Cement	33.70
Lumber	10.00
Gravel	30.00
Rock	7.25

Estimates published by the Western Canada Loan Company, Limited, (an English incorporation), place the initial cost of equipping the collieries of the Pembina Coal Company at $250,000. This latter company is subsidiary to the Canada Land Company. A purchase price of $500,000 was paid for the coal lands. The output counted upon is 1,000 tons per day. Messrs. Bambridge, Seymour & Company, of London, Eng., reported upon the Pembina fields.

THE PORCUPINE GOLD DISTRICT.

HAMLIN BROOKS HATCH,

The Porcupine gold area comprises about 216 square miles, surrounding Porcupine Lake, in New Ontario. The lake is forty miles due west of the 222-mile post of the Temiskaming & Northern Ontario Railway, which connects the Town of North Bay with the new Trans-Continental. Part of the area is surveyed and consists of the Townships of Tisdale, Whitney, Shaw, and Godfrey. The remainder lies in the Temagami Forest Reserve.

History.

The gold-bearing quartz bodies of the district first attracted attention in the late fall of 1909. The announcement of the discovery of auriferous quartz bodies was followed by an unprecedented rush of prospectors to the new field. This rush continued for perhaps two months into the winter, and during this time. all the available ground was staked for miles in every direction. The means of transport were canoes and packsacks until the freeze-up, when roads were cut and sleighs and toboggans came into use.

Topography.

The Porcupine area is probably a portion of the great post-Laurentian and pre-Huronian peneplain. It is undoubtedly proven that the deposits of the Huronian and Cretaceous periods were followed by a period of erosion, which developed the peneplain. The area under consideration was concerned in all these changes and the continued erosion has so thoroughly worn away the hills that the present surface has all the aspects of a characteristic peneplain.

The present surface is traversed by low-lying quartz-bearing schist ridges, the highest elevation attained being in the neighbourhood of seventy feet. The surface is even, and the overlying drift in most cases is extremely light. In parts of the district there are sand and boulder moraines, which are of both the terminal and lateral kind. It may be said that the whole gold-bearing area has been so eroded that the only formation which has exerted any resistant influence, whatever, upon the topography, has been that of the quartz bodies themselves, which, on account of their extreme hardness, did not lend themselves readily to the agents of erosion.

Geology.

Owing to the recent discovery of the district and to the fact that until very recently the country was snow-covered, only a very general idea of the geology of the district has been obtained. The only formation so far met with in the gold-bearing area are of igneous origin and may be classified as follows:

1. Schist—green in colour, and showing marked schistosity.
2. Igneous eruptives—diorite, diabase and porphyry.

It may be said that the geological history of the district began with the plutonic formation of a basic igneous rock, which later by metamorphism took on its present schist form. The gold-bearing quartz bodies, so far, have only been found in the schist formation, which covers the greater part of the whole prospected area. This schist is undoubtedly of igneous origin and presents all the characteristics of being an altered plutonic diorite. It is green in colour and the schistosity runs parallel to the general strike of the whole formation, which is northeast. In the vicinity of the quartz bodies it is heavily pyritic, and in all specimens examined by the writer, pyrite was present. In mineralogical composition it is closely allied to the eruptive diorite, the only difference, as nearly as can be determined by the naked eye, being one of structure. In places the writer has noticed the gradation of the schist formation to that of almost typical diorite, the transition being so gradual that the line of contact was not discernible. Further investigations and further development of properties may, perhaps, alter this hypothesis, but at present all indications are that it is correct. The extent of this schist is practically over the whole gold-bearing area, it being approximately 18 miles east and west, and 12 miles north and south. Dykes of some of the basic eruptives cut it occasionally, two of these dykes having been noted in Shaw Township cutting across the strke of the formation. In Whitney Township diorite dykes have also been seen. In contrast to the diabase dykes, these appear to cut the formation parallel to the schistosity. Also in Shaw Township there has been reported to the writer a quartz porphyry intrusion, but as yet this has not been verified.

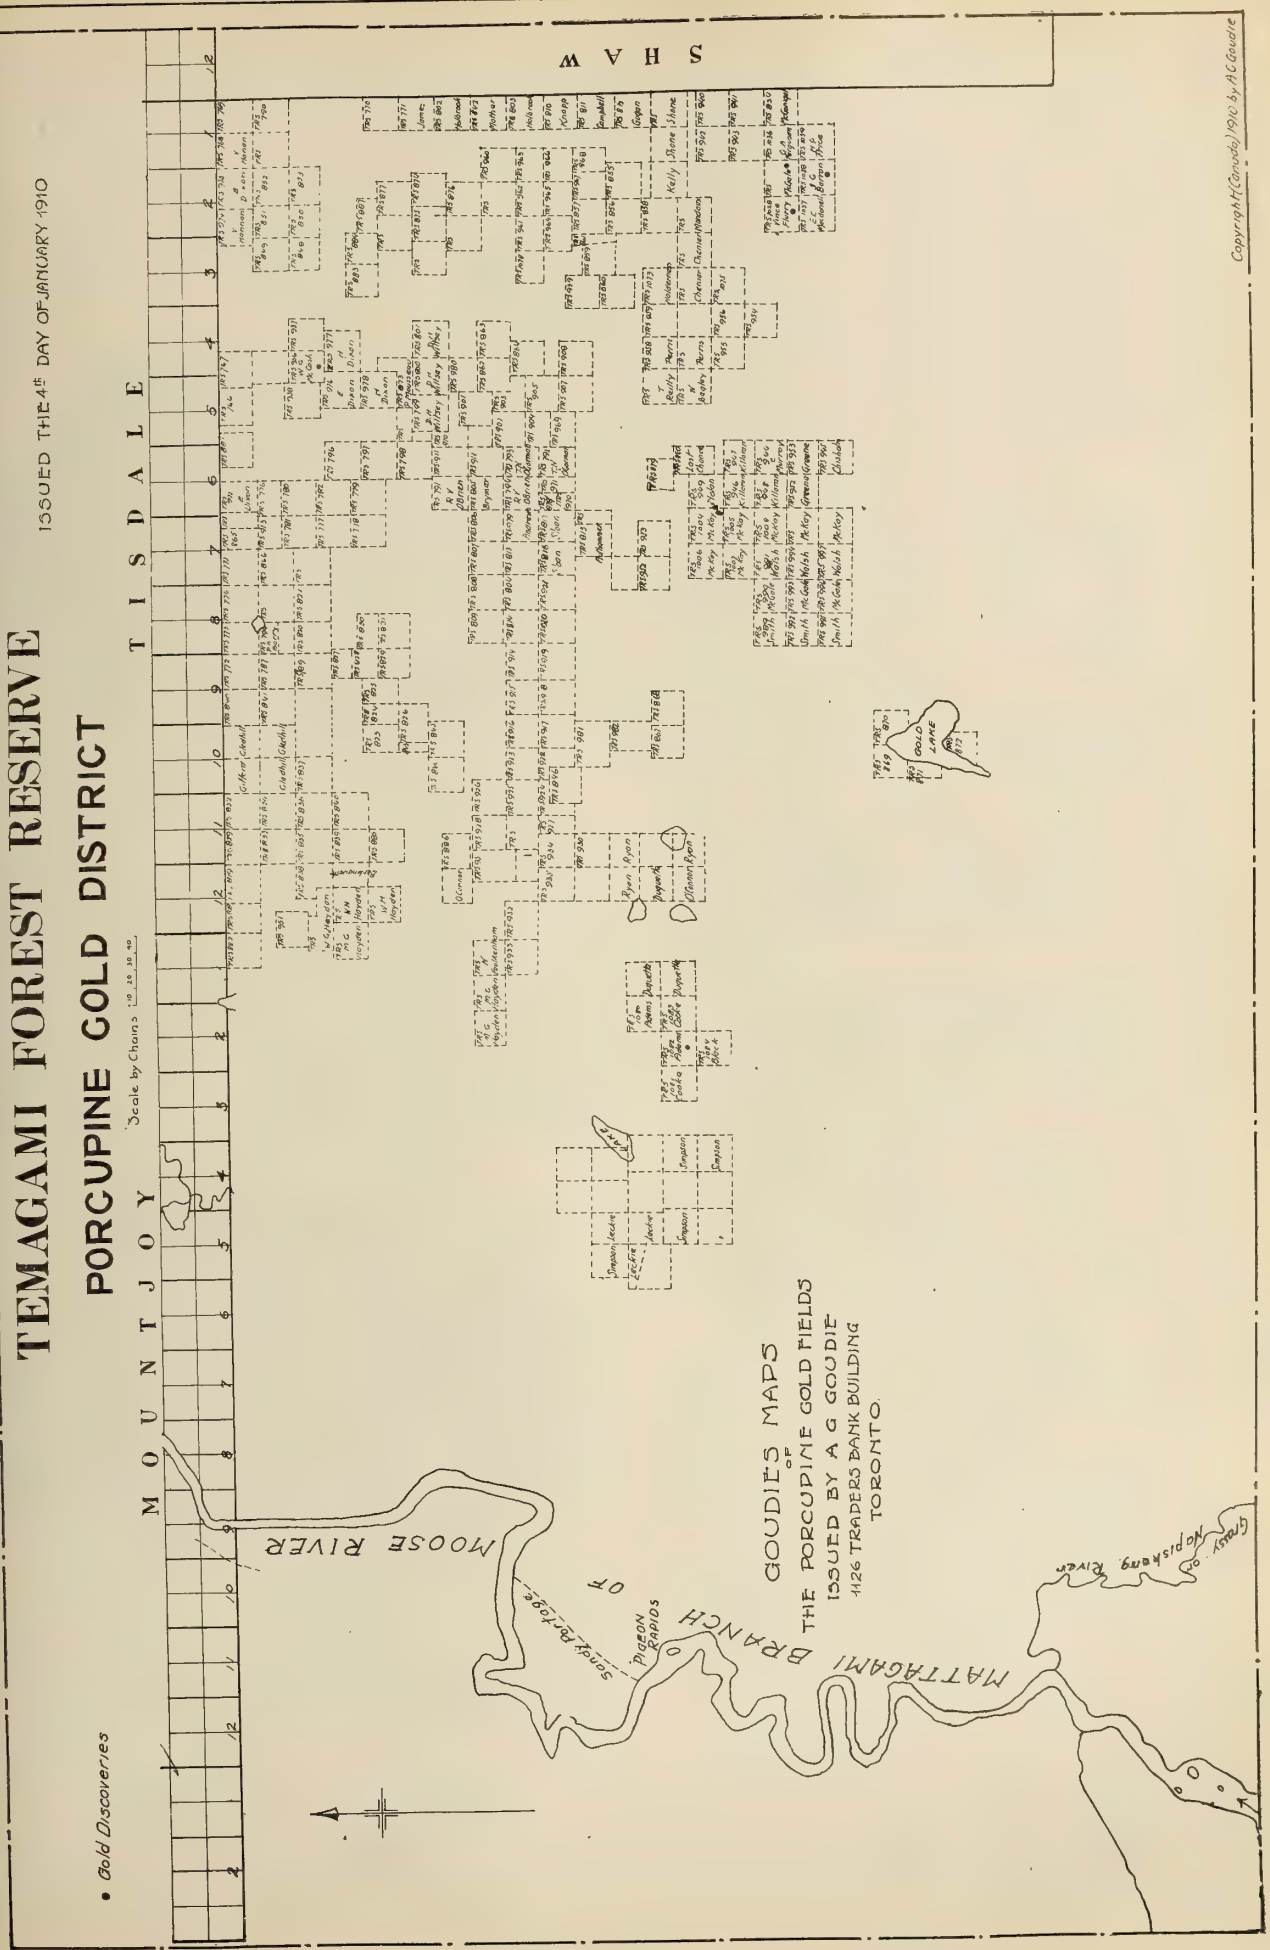
Ore Deposits.

The auriferous bodies of the district so far discovered may be divided into three classes:

1. Segregated veins.
2. Fissure veins.
3. Fahlbands.

The segregated veins are a series of overlapping quartz lenses, which vary greatly in size. In some cases the lenses form extended deposits, although each of itself is of no great extent. They appear to be formed along certain well-defined lines of weakness, which are lines of local faulting. In many instances they are auriferous and carry pyrite in greater or less quantity. The general strike of the veins of this type appear to be northeast and follow the schistosity.

Fissure Veins.



These are quartz veins, which cut the formation in all directions and vary greatly in size. The writer has observed them from one inch up to well-defined veins of fifteen feet. Some show native gold, and practically all give assays. Their longitudinal extent is not known at the present time as this type of deposit is almost invariably covered with drift and has only been exposed in places where assessment work has been done.

Fahlbands.

These deposits are beds of foliated schist, impregnated with sulphides. Copper sulphides and iron sulphides are common. As a rule they are from 100 to 200 feet in lateral extent, and in certain instances have been followed longitudinally for 500 feet. Shaw and Whitney Townships, and the Temagami Reserve—just south of Tisdale—furnish the best examples of this type. In some cases free gold has been found in minute quantities on the surface of these deposits, and in several instances assays of the sulphides have also yielded values.

Economic Possibilities of the Porcupine Area.

At the present stage of development of the district it is, of course, impossible to determine definitely whether Porcupine will or will not become a paying gold camp. There are several fine looking properties

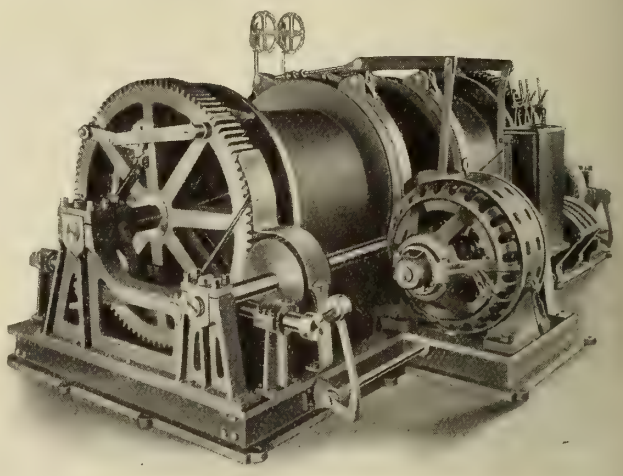
in the district, notably the Wilson Dome, and the Timmins option, which undoubtedly have all the aspects of becoming paying mines. Both of these properties have on the surface enormous quartz bodies carrying spectacular free gold in quantity. In so far as development has proceeded on them, the ore bodies have shown no lessening of values. The Timmins people are at present down in the neighbourhood of 100 feet, on their ore body and have sacked ore and have sent a car-load to the States for a mill run.* The returns from this mill-run will go far to prove or disprove the worth of the district. On several other properties where development work has been done it is encouraging. It would be of benefit to the different claim holders and the investing public at large, if the results of the work now being done would be frankly stated. The writer knows that results so far are encouraging and that the chances of the district becoming economic are more favourable each day. It must be understood that there is very little ultimate chance of the district being other than low grade. It may be added that the question of power is one of moment and will probably be solved eventually by the utilization of two water powers, which are within easy striking distance of the district.

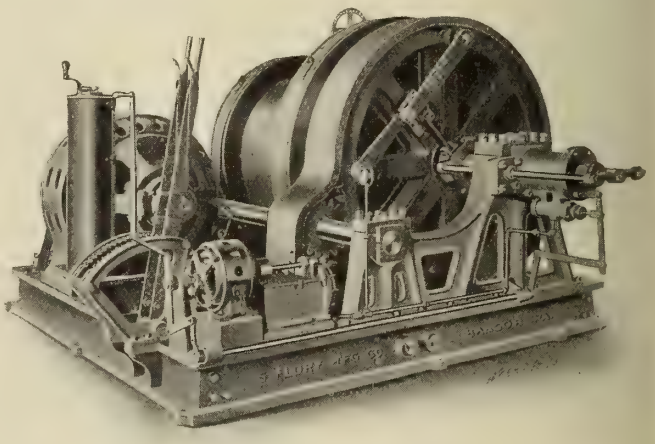
In conclusion the writer wishes to say that the encouraging results so far obtained on those properties on which development has gone ahead, makes him of the opinion that this newest Ontario gold field will eventually become a paying producer.

*Editor's Note.—This carload is reported to have averaged $200 per ton. As to the value of this shipment sample from an engineering point of view, the reader is referred to the editorial on another page.



ELECTRIC MOTOR DRIVEN MINE HOISTS.

Since the cycle of operation in any hoisting proposition is of an intermittent character, the power is at a maximum only a part of the time, even though the hoist be operated practically continuously. In many cases the hoist is in operation only a very small part of the day. These conditions offer special advantages from an economical point of view for the use of electric motor-driven hoists. The electric hoist is always ready, and uses power only in proportion to the load handled when it is in actual operation.



The bearings are self-oiling and the motors seldom require any other attention than an occasional inspection and cleaning. There are no complicated parts to get out of order or to require continual oiling, packing, etc. The electric hoist may be operated by almost any one, as no previous experience or mechanical knowledge is required and an engineer's license is unnecessary.

The single and double drum motor-driven mine hoists of the S. Flory Manufacturing Company, Bangor, Pa., are well shown by the accompanying pictures. These hoists which are especially designed for mines, quarries, planes, shafts, etc., are equipped with the I. O. Werner patent band friction and are driven by Westinghouse motors.

The patent band friction is of special design and possesses many features of superior merit. It is actuated through different members: the gear, drum, rocker shafts and strap bands. The strap bands tighten on a cast rim on the drums and are actuated by shafts which have double stub ends and are connected to the ends by jaw ends and turnbuckles. The lever arms are keyed to the rocker shafts on opposite ends and are actuated by the levers which move around fixed points on the gear. Slides are secured on the gear supporting the lever arms. The slides are actuated through a sleeve on the main drum shaft, and two radial arms which are secured to the slides. The frictions are thrown in and out of contact by means of hand levers in a battery, as shown by the cut of the double drum hoist, or by an air cylinder using an equipment similar

to street railway car compressors, as shown by the picture of the single drum hoist. By moving the sleeve to the gear the slides are actuated in a radial direction that operates the stub levers and rocker shaft; this causes the band to grip or tighten on the brake flanges of the drums. The reverse motion of the sleeve releases the fricton. A strong claim is made for the gripping device. After the frictions are thrown into contact, they will positively remain in this position until released. The drum and gear form a unit and can be operated as a reverse motion hoist without producing

any end strain on the bearings; the value of which is obvious. When the frictions are thrown out of contact, the drums are loose on the shaft and will revolve free at high speed when lowering or paying out the rope.

The single-drum hoist is shown with a Westinghouse electric railway air compressor and air reservoir mounted on the base of the hoist. The reservoir is connected to the air cylinder at the end of the drum shaft. The air valves are actuated by a lever shown

close to the battery of two levers and controller. Very little exertion is required by the motorman to throw the friction in and out of contact as it is of the toggle type. After the air compressor is put on the contact continues until the friction is reversed by the reverse motion.

The drums are turned off smooth or machine spirally grooved for any size wire rope, and mounted on a self-contained cast iron base arranged to receive the motor and controller. The drums for long planes or heavy lowering are equipped with asbestos brakes made out of long fibre material. The blocks are formed in sectors with iron flanges, securely bolted under high pressure, and treated with oil. They are secured between cast iron flanges and surrounded with steel bands of the differential type. The brake bands are operated with hand levers in notched quadrants fitted with thumb latches, and are thereby securely held in any position. The advantage of asbestos brakes for long planes or shafts is decided.

The single drum hoist shown by the photograph was installed at the Bliss Colliery of the D. L. & W. Company. The drum is 60 inches in diameter; 48 inches long between the flanges, and is designed for an 8,000-pound rope strain at a speed of 500 feet per minute. The hoist is operated by a Westinghouse type "HF" 150 horse power alternating current motor. This type of induction motor is especially suited for application where a strong starting effort is needed. It is well adapted for use on circuits carrying lighting loads, as the starting of it does not appreciably affect the voltage regulation. These motors are controlled by standard Westinghouse single handle, reversing, drum type controllers which insert resistance in the secondary at starting, and gradually cut it out as the hoist speeds up; the controller has a large number of points that gives smooth acceleration. When the controller is in the off-position, the motor is entirely disconnected from the line.

The double-drum hoist shown was installed for the Bessemer Coal, Iron & Land Company, Messins, Ala. It is connected to a Westinghouse 125 horse power motor of the same type.

CORRESPONDENCE.

*DR. HAANEL'S LETTER TO THE TEMISCAMING MINE MANAGERS' ASSOCIATION.

Ottawa, April 7th, 1910.

DEAR SIR:—

I am in receipt of a letter dated March 31st, 1910, entitled "Statement by Temiskaming Mine Managers' Association," from which I learn that the Association in question has thought it advisable to criticize me personally for certain statements which were included in an address delivered by myself, at the request of the Honourable Clifford Sifton, before the Canadian Conservation Commission. In making this statement, the Cobalt Mine Managers' Association has acted without a full knowledge of the facts. Considering the statements seriatim:—

1. That the statements "and in the Cobalt Region . . . . the mortality was simply astounding, the death rate per 1,000 men employed being 24.8," is absolutely without foundation or fact.

The figure given above was supplied to me by a trained mining engineer who had been especially engaged to make statistical investigations of this nature. That he misinterpreted the data published in the 18th Annual Report of the Bureau of Mines for Ontario is no fault of mine. Officially, I am responsible for his work; personally, I have no responsibility as I cannot be expected to personally check all data supplied to me by my subordinates. Had his figures been correct, my remarks would have been truly justified. As it happens, this officer is not alone in having made this error, for the same data have also been misunderstood by a number of other parties. Precisely the same figures were given independently by Honourable Clifford Sifton in his opening address before the Conservation Commission, and data for Mr. Sifton's address were not supplied from my office.

2. "That knowledge of its incorrectness was known by those responsible for it, two months previous to its publication in the above periodical."

This statement is without foundation in fact, as the following correspondence will show:

*See page 241, C. M. J., April 15th.

26 Wellington Street, Ottawa,
December 8th, 1909.

T. E. Corkill, Esq.,
Inspector of Mines, Toronto.

DEAR SIR,—I am looking up statistics on mine accidents and have read with much interest your remarks on this subject in the Annual Report of Bureau of Mines, 1908.

In your report I do not see any information given as to the number of persons employed underground, and above-ground, or total employed.

In Part IV. Colonial and Foreign Statistics for 1907 the total number of men employed is given for Ontario, as also the number of deaths, and death rate per 1,000.

I would appreciate your kindness very much, if you could supply me with the following information, form of which I enclose.

Yours truly,
(Signed) J. G. S. HUDSON.

DEPARTMENT OF LANDS, FOREST AND MINES.

OFFICE OF THE BUREAU OF MINES.
Cobalt, December 13th, 1909.

Jos. G. S. Hudson, Esq.,
Department of Mines,
26 Wellington Street, Ottawa, Can.

DEAR SIR,—I am in receipt of your letter of the 8th instant, asking for information regarding the mine accidents in Ontario for 1908. I will look into this matter as soon as I go to Toronto and give you the data asked for.

I must say, however, that the number of men employed underground in the Cobalt Camp in 1908 was more than 1,089. You have received this number from Mr. Gibson's statistics which is quite correct for the producing mines. I would draw your attention to the fact that there are only some thirty or thirty-five producing mines in the Cobalt Camp, which would not be half of the number of mines that are in operation.

Your truly,
(Signed) E. T. CORKILL.

You will note that Mr. Corkill writes: "I will look into this matter as soon as I go to Toronto and give you the data asked for." Mr. Gibson stated, both publicly and privately, in Toronto, that he personally had had no correspondence on this matter from this Department. I, also, can state that I had no correspondence on the matter, and can add that I had no personal knowledge of the correspondence noted above. I was surprised to learn from Dr. Wilson, on his return from Toronto, that there had been any correspondence. You will note that the two letters which have been exchanged are entirely unofficial. You will also note that Mr. Corkill promises to send the information for which Mr. Hudson asked. These letters were referred to both publicly and privately by both Mr. Corkill and Mr. Gibson in Toronto, during the meeting, but the information asked for in Mr. Hudson's letter and promised in Mr. Corkill's letter of December 13th, 1909, has not yet been received at this office.

Further, Mr. Corkill's letter is dated December 13th, 1909, the address was delivered on January 19th, 1910, and the same day the manuscript was handed to the representative of "Industrial Canada," at his own request. Proof was never submitted to me, and at the time of its publication I was not even aware that an error had been made.

3. "That notice of their error has still more recently been brought to their attention, both publicly and by the Ontario Government."

My attention was drawn to the error by an officer of this Department, and, subsequently, under my direction, this same officer, acting officially, made personal inquiries in Toronto with respect to this matter. The Ontario Government has not otherwise held any official communication with me on the matter, and has not sent a written statement officially drawing my attention to the error. Such information as we now possess has been obtained as the result of our own initiative and by personal inquiry.

4. "That in issuing no formal correction, those responsible for the statement are to be condemned for their silence and defensive attitude."

Dr. Alfred W. G. Wilson, who made the inquiries for me in Toronto, made a written report to me on March 7th, the date of his return from Toronto. The same morning the substance of this report, correcting the error, and giving the rate of 11.94 fatalities per thousand for the "Silver-Producing Mines" of Cobalt, was transmitted to the Honourable William Templeton, Minister of Mines. A report by another officer, dealing with mine accidents and which was in the printer's hands, was recalled and the necessary corrections were made. That these reports have not yet been published is not due to the inaction of this department. It did not appear to me that any further action was immediately necessary. Public attention had been called to the matter officially by an officer of the Ontario Government. No sensible person would think for a moment that such a mis-statement was made by me or by any one else in this department intentionally. Why should a special public statement be issued by me withdrawing the figure in my personal address on the authority of another party, and substituting therefor one equally startling, Equally startling because, if we accept, as you have done, Mr. Gibson's statement that there were thirteen fatalities in the "Silver-Producing Mines" of Cobalt, then there were fourteen fatalities in the non-producing mines of the same locality, and obviously there were fewer men working underground in these non-producing mines, although we have no published data as to this number. To strike any ratio for these non-producing mines would be a mistake under the circumstances, but what advantage would there be in correcting the former error and leaving the matter open to still greater error? Moreover, we already had in press, in the form of a report, a document in which there is a correct statement based on Mr. Gibson's own figures. Why then recall the former figure when the correct figure is given in an official report to be issued by this department?

The purpose of the statement in the original address was not to draw attention to the precise fatality rate of Cobalt. That is an abstract matter and incidentally of little importance. The statement was made purposely to show that the death rate was abnormally high and to draw attention to the matter, that it might be remedied. In such a connection, the precise rate per thousand is a matter of little moment. It would seem that the original purpose of that portion of the address which referred to mine accidents has been abundantly fulfilled.

5. This statement gives what purports to be the official figures on fatalities.

As already stated in section 2 above, Mr. Corkill promised, unofficially, in his letter of December 13th, 1909, to give us data asked for. These data have never been received either from Mr. Corkill or from Mr. Gibson. This table in your statement of the ratios is the first that has been seen either by myself or by any officer of this department. The figures are not given in any official publications of the Ontario Bureau of Mines that have been received at this office. That officers of my department, officers of another department not connected with the Mines Branch, and certain independent citizens of Ottawa, Halifax and elsewhere, have failed to clearly understand the data published in the reports of the Ontario Bureau of Mines is due either to their stupidity or to the manner in which the information in these reports is worded. Which is to blame is a matter of opinion. You will note, on referring to a statistical table subjoined herewith, that Mr. F. L. Hoffman, Statistician of the Prudential Insurance Company, of New Jersey, strikes a ratio of 9.94 fatalities per 1,000 employees for the silver and cobalt mines of Ontario in 1908. Evidently, authorities can honestly differ even when working with the same data.

6. Nothing in this statement was intended to reflect in any way on the excellent work which is being done in Canada at the smelters referred to. You will find, however, from the reports of the Ontario Bureau of Mines and from the reports of the Temiskaming and Northern Ontario Railway Commission, that these smelters export a large percentage of ore for further treatment. On page 12 of the 18th Annual Report, it is stated: "Through these works there were passed an aggregate of 6,958 tons of ore, containing 11,658,008 ounces of fine silver ,of which 8,972,938 fine ounces were recovered, the remainder. 2,685,050 ounces, being contained in the speiss product, reserved or exported for further treatment."

On analysis, this shows that 23.03 per cent. of the silver in the ores received by these smelters is recovered elsewhere. The same report is my authority for the statement that a large tonnage of low grade ores is exported, and that at present the elements other than silver are of comparatively little value, at any rate to the miners of the ore.

7. With regard to the statement of this section, it is only necessary to remark that no officer of my department should be blamed for obscure statements publish-

ed in the reports of the Bureau of Mines. Other persons entirely outside of this department and independent of it have misunderstood these reports in precisely the same way.

Here follows an illustration of Dr. Haanel's point, taken from a contemporary.

We recognize the excellent work of the Province of Ontario and her inspectors as regards the mining and inspection laws. The high mortality figures, as compared with foreign countries, and especially with Germany and England, show that there is still room for further improvement, and Ontario is not the only province in which this improvement is required.

8. This statement requires no comment.

In conclusion I would ask your association to consider the circumstances under which the address, afterwards published in "Industrial Canada," was delivered The purpose of the meeting was to consider Conservation in all its aspects. Is it not desirable that throughout our mining districts there should be greater care of human life and property? Are not the fatality rates in our mines, particularly underground, unnecessarily high? Can this rate not be reduced? And in regard to the treatment of the Cobalt ores, are not methods of treatment which will enable us to recover the whole of the silver values in Canada desirable? Would it not be of direct benefit to the miner and to the country at large, if the Cobalt content of these ores could be recovered and economically used in Canada? As it is, practically all the cobalt, except the very small percentage saved as a pigment, is lost to Canada. Are not these fit subjects for discussion before such a convention as the Conservation Commission, and are they not worthy objects in investigation? The mere fact that a slight error was made in quoting a mortality figure, an error entirely unintentional and due to causes beyond the control of the speaker, should not be allowed to detract from the force of the argument there set forth, nor should it call for more than passing comment.

I hope that you will see fit either to give this letter the same publicity accorded the statement which has caused it to be written, or that you will reconsider the statement in the light of the facts here set forth.

Yours very truly,

EUGENE HAANEL,
Director of Mines.

PRESIDENT PARK'S REPLY.

Dr. Eugene Haanel,
Director, Mines Branch, Ottawa, Ont.

DEAR SIR,—In reply to your letter of April 7th, regarding statement made by this Association.

While appreciating the detail of your reply, we cannot see that it alters or rectifies any of the statements taken exception to. We see no necessity of our replying at length and becoming involved in controversy. We cannot pass over, however, the fact that the copies you give of correspondence between J. G. S. Hudson and E. T. Corkill, are not complete, on the part of Hudson. He especially mentioned 24.8 as the result of his calculations, and it was to this letter and result that the reply of Corkill, which you give, was intended.

We recognize that improvement is always possible in metallurgical treatments. We believe that Thorold and Deloro are recovering practically all values of all marketable constituents, even to the point of exceeding the demand. That such is not done in Canada, at Copper Cliff, we believe, is entirely a matter of industrial conditions, and which is also governed largely as to the location of their markets. The fatality percentages are those as given by Mr. Corkill, who after all, is the only person competent to determine them.

We believe you lay too much stress on what is official and what is unofficial. Although you acknowledge an error on the part of one of your assistants, we see no reason why, in a public matter receiving a public protest, you prefer to place the correction in the hands of a printer of an official document, to appear at an indefinite date.

According to your request for equal publicity, we are sending copy of your letter to the CANADIAN MINING JOURNAL.

Yours truly,

H. PARK,
President.
J. G. SHEWAN,
Secretary.

Cobalt, April 26th, 1910.

The Editor, CANADIAN MINING JOURNAL,
Toronto, Ont.

SIR:—Mr. S. G. Forst, of Toronto, a director of the Peterson Lake Silver Cobalt Mining Company, has recently issued a circular letter to the shareholders, in which he casts insinuating reflections upon the character of his co-directors and also against the secretary-treasurer and solicitor of the company. Many of your readers have probably seen the letter, and it is probably too long to be printed in its full text.

In this letter Mr. Forst states that I rendered an account of $4,800 to the Peterson Lake Company for the work done in connection with the Nova Scotia investigation last year, and that I am still the holder of a lease on Peterson Lake granted to me in 1908. Both these statements are absolutely false. He also intimates that Mr. R. F Segsworth in his capacity as secretary-treasurer, was instrumental in having me appointed and in paying me a large fee for work done, and was using his influence to have the leases extended on account of his relation to me.

I do not need any defence with those who have known me during my fourteen years' mining experience, but to those who are not acquainted with Mr. Forst and his methods, or with myself, the following plain statement of facts is due.

After some pressure I was induced to undertake (at the personal solicitation of the president), the investigation, and was appointed on the 8th day of June, 1909, on the motion of Mr. Forst, and my fee for the work arranged. I returned to Toronto and made a partial report to the directors, and on the 30th day of June, on the motion of Mr. Forst, was instructed to return to Cobalt and make a more extended investigation. On the completion of the work, Mr. Forst moved the acceptance of the report, and it was also adopted by the shareholders at a general meeting held on October 6th, 1909. I did considerable work during the fall and winter in connection with the litigation and my account was not presented until March. 1910, when Mr. Forst attempted to repudiate the whole transaction and began the personal attack above referred to, apparently to gain full control of the company for himself.

I obtained a lease from the Peterson Lake Mining Company in April, 1908, and in the same year sold it to the Kerry Mining Company, and from that time have had absolutely no connection with the management or financing of that company. My brother is not a direc-

tor of the Peterson Lake Company, and has no vote on the board, and accepted the position of secretary-treasurer at the personal solicitation of Mr. MacLaren and Mr. Scott, and was appointed on the motion of Mr. Forst some time after my own appointment.

Mr. Forst says in his letter, "One of the leading engineers of Cobalt has informed Mr. Forst that he would have done the required work for $1,200." It is unusual for prominent engineers to state the cost of this class of work before its execution, and it is more unusual for them to comment upon the cost of extensive examinations made by others unless they take pains to inform themselves of all the work done. In this case I am sure that the engineer's so-called prominence exists in Mr. Forst's imagination, or that he was misquoted.

A slight consideration of the above facts will show that Mr. Forst must have some ulterior motive for repudiating his own actions just five weeks before the annual meeting. He holds to be unjust and iniquitous acts in which he was the prime mover, and the results of which he moved to accept, and then states that they were wholly the acts of others. His position is so false and unjust that further comment is unnecessary.

Yours truly,

Walter E. Segsworth.

Toronto, May 4th, 1910.

THE GEOLOGICAL SURVEY FIELD PARTIES SO FAR ARRANGED FOR ARE AS FOLLOWS.

Mr. D. D. Cairnes will examine the ore deposits of the Atlin district. Since the early days of placer mining a number of mineral veins have been discovered.

Mr. R. G. McConnell, assisted by G. O. Malloch, will study the country at the head of the Portland Canal. This district has recently come into prominence, and a mining boom is now setting in.

Mr. W. W. Leach will continue his explorations in the Hazelton district, on the Grand Trunk Pacific Railway, up the Skeena River.

Mr. C. H. Clapp will continue his geological investigation on the southeast end of Vancouver Island.

Mr. R. H. Chapman will continue topographical work on Vancouver Island.

Mr. Chas. Cassell will complete the geological mapping of the Tulameen district.

Mr. L. Reinecke will continue the mapping of the Beaverdell district, West Fork Kettle River.

Mr. O. E. LeRoy will complete his study of the geology and ore deposits of the Slocan district and investigate Deadwood Camp, Boundary Creek district.

Mr. W. H. Boyd will be engaged in topographically mapping these districts.

Mr. R. Schofield will continue work in East Kootenay.

Mr. J. Allan and Mr. Shimer will make a geological study of the Ice River district.

Mr. D. B. Dowling will continue his investigations of the coal areas of Alberta, near the Grand Trunk Pacific Railway.

Mr. W. McInnes will explore in the country north of Prince Albert.

Mr. H. Ries and J. Keele will be engaged in a study of the clay deposits of the Northwest Provinces.

Mr. J. D. Trueman will map the geological formation about Gunflint Lake.

Mr. W. H. Collins will be engaged in a geological study of the country west of Gow Ganda.

Mr. W. A. Johnston will complete his mapping of the Lake Simcoe district.

Mr. C. R. Stauffer will make a detailed study of the rocks of the southeastern peninsula of Ontario, which are important on account of oil, gas and salt.

Mr. M. E. Wilson will explore the country near the Transcontinental Railway east of Lake Abitibi.

Mr. J. Dresser will continue his investigations in the Eastern Townships.

Mr. E. R. Faribault will spend part of the season in the Chibougami district as a member of a geological commission sent out by the Quebec Government.

Mr. J. W. Goldthwait will study the Pleistocene geology of the St. Lawrence valley.

Mr. G. A. Young will geologically survey the Tobique district.

Mr. M. Y. Williams will be engaged in a geological investigation in the Arisaig district.

Mr. E. R. Faribault will have a party continuing the investigation of the gold-bearing rocks of Lunenburg County.

In addition, it is hoped that a number of competent geologists will be secured to undertake pressing work in the Northwest, in Ontario and in Nova Scotia for the new Museum.

SAND FILLING OF STOPES.

At the Robinson gold mine on the Rand the hydraulic sand filling of stopes was undertaken last year on a small scale, and the consulting engineer now reports that arrangements are being made for the application of the scheme on more extensive and practical lines. "This system," he says, "provides security in the old workings. It will enable us to win nearly all the rich pillars left on the main reef leader and south reef, and will assist in the economic working of the main reef." Other Rand mines are also about to employ the sand filling process to a much greater extent than hitherto. Mr. Schumacher, at the Rand Mines meeting last month, suggested that in the course of the next five years the unsightly sand dumps of the Central Rand will have partially disappeared. The plants now in course of construction or already complete will, at an early date, be dealing with sand at the rate of about 4,000,000 tons per annum. As soon as these are in proper working order steps will be taken to increase the capacity of the sand-lowering equipment until the dump heaps of the Central Witwatersrand will be depleted at the rate of 30,000 tons per day, or, approximately, 9,000,000 tons per annum, an amount which is more than double the total tonnage mined by the Rand Mines, Limited, last year. The plan required for carrying out these operations is very simple indeed, and consists of a sand-bin at the top of the shaft, into which dry sands are filled from the nearest dump. A pipe is led from this bin down the shaft and along the drives, etc., to the point at which it is desired to pack. Down this pipe the sands are flushed with water, under a free flow. The water is drained off at the top of the beds of sand packing and is re-pumped to surface for use again. This water is kept wholly apart from the mine water. The preceding remarks apply, of course, to accumulated products only. For the time being it is deemed inadvisable to employ current sands for the packing work, as they naturally carry a considerable amount of free cyanide, and are, moreover, not sufficient in themselves to provide all the material required. Experiments are, however, being carried out with a view to neutralizing the contained cyanide in current or recently dumped products.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay, May 3rd, 1910.—The Close of the U. M. W. Strike. In our letters which appeared in the Journal of the 15th of March and 1st of April we referred to the desire which was being shown by the management of the Dominion Coal Company to afford their striking employees an honourable way out from the mistaken position which, under the tutelage of the U. M. W. A., these men have taken up. We referred to the efforts of the clergymen of the Glace Bay district in this direction, and to the circumstances under which the company saw fit to withdraw a written statement from the general manager of the terms on which they were willing to re-employ the strikers, and we remarked: "Whoever counselled the men on strike to refuse the very liberal and honourable offer which was made by the management of the company in their desire to end a situation, disastrous to all alike, assumed a grave responsibility. The strike was always unnecessary, and those who called it were guilty of crime, but its continuance under present conditions is merely foolishness. The individual strikers are beginning to realize this, and the increasing outputs tell their own unmistakable tale." The reasonableness of the company's position was admitted on all hands, and the illegality of the proceedings of the U. M. W. A. was clearly laid down by Judge Lawrence's decision and the restraining order which he issued against the American union. The efforts which had been made two months previously to end the strike, to which the company had responded in a very conciliatory manner, were still continued by the clergymen, and the sentiment against further futile prolongation of the strike became almost unanimous, and too pronounced to be resisted. The United Mine Workers are face to face with a large strike expenditure in their own proper domicile, and they are also having trouble in the Canadian West. One of the most prominent of the U. M. W. leaders made the statement that the strike had been mismanaged and was commenced under a misapprehension of the true state of affairs, and in face of the action, which the Coal Company has entered against the U. M. W. for damages and conspiracy, and the large importations of men which the company was arranging for, the leaders of the U. M. W. appear to have concluded that the present time was not opportune for further prosecution of the strike, which on their own representations has absorbed the entire amount at the credit of their reserve fund in July of last year. The offers which the company has made from time to time to take back its striking employees and give them absolutely fair treatment have always been open to the men, and acting upon the advice of their leaders the strikers decided to return to work, relying on the good faith of the company to deal fairly with all its employees. The end of this ill-starred trouble, like its commencement came with remarkable suddenness and took people generally by surprise. The past ten months has been probably the most unpleasant period that Glace Bay ever experienced, and there can be no doubt about the sincerity of the general hope that the trouble is over, and that its memory will be as evanescent as that of a hideous nightmare. The strike was an ill-considered and ill-advised proceeding, taken with a blind disregard of the probabilities. Its utter failure was apparent the first week of the trouble, and it is a great pity that the fighting abilities of those who took part in the strike were not utilized to better advantage than to serve the aims of an ambitious labour leader and to destroy the livelihood of the fighters themselves.

A New Work on Nova Scotia Mining Industries.—Mr. C. Ochiltree MacDonald has enriched the mining literature of Canada by what is undoubtedly the most complete survey of mining in Nova Scotia which has appeared since Mr. Richard Brown published the "History of Coal Mining in Cape Breton." Mr. T. J. Brown, in his presidential address before the Mining Society of Nova Scotia, recently deplored the fact that Mr. Richard Brown had apparently no successor in his literary labours in this connection, but it would appear as if the mantle of this worthy of former days had descended on Mr. MacDonald, who we believe is also from the "Old Country." A casual reading of Mr. MacDonald's book impresses one with the fact that he views the coal mining industry of Nova Scotia with a breadth of view and with a sanity proceeding from a complete apprehension of the facts and the history of the industry, and the work will repay perusal by anyone whose business touches coal-mining in this province.

Referring to the Dominion Coal Company, the author remarks: "The organization of the Dominion Coal Company has obviously very greatly benefitted Nova Scotia; and all Eastern Canada has similarly felt the beneficial effects of this timely amalgamation of the collieries south of Sydney Harbour." Mr. MacDonald states that had the Dominion Coal Company not been formed a shortage of coal must have come about "which would have abnormally increased the price of fuel to the Canadian consumer."

In connection with submarine coal-mining, Mr. MacDonald speaks from personal knowledge of the subject obtained at the Morien collieries. He refers to the great submarine coalfield lying off the shores around Sydney Harbour, which, "lying on the edge of the water routes to the most populous markets in the globe, is practically inexhaustible; and the Sydney coalfield may consequently be regarded as one of the world's greatest coalfields." It is a matter for surprise that many people do not realize the value of the Sydney coalfield. When it is considered that it is the only coalfield on the Atlantic seaboard of the American continent—the other Nova Scotian fields alone excepted—that the coal measures of Europe and the United States are becoming very sensibly depleted, and that the world's future coal supply lies mainly in Siberia and the Far East, there are, it would seem, very sufficient reasons to anticipate a marked appreciation in the value of the Cape Breton coalfields. Mr. MacDonald also refers to the wastefulness which would be occasioned by adherence to the regulations governing submarine mining which until lately were law in Nova Scotia. It was always understood, however, that these regulations were merely tentative, and would be modified as experience was gained in working submarine coal areas. Mr. MacDonald remarks very truly that submarine areas "can be more advantageously wrought by specific regulations applied to each as experience in the winnings accumulated, rather than by hard and fast rules equally applicable to all." Most people will agree with this point of view.

The book deals very sympathetically with the history and aims of trades unionism in the province, and traces the history of the Provincial Workmen's Association from its commencement under the direction of Mr. Robert Drummond. Mr. MacDonald refers to the changing conditions brought about by the recent industrial expansion in Cape Breton. He remarks that the mine workers of Nova Scotia have in the past" by their moderation, patience, and good judgment promoted the development of the Nova Scotia coal trade; and by the exercise of similar good judgment they can further promote this great industry." These remarks are peculiarly opposite to the condition now existing at the Glace Bay Mines, where the hitherto harmonious relations existing between the mine-workers and the operators have been disturbed by the intrusion of influences alien to the province. It is to be hoped that the present situation will be helped by what Mr. MacDonald terms "the pacific influences likely to be exerted by the hereditary intelligence of

the Nova Scotian mining classes, and the fair treatment the mine-workers enjoy from the operators. Mr. MacDonald is evidently among the prophets.

The book makes reference to the suitability of many of the fireclays associated with the coal seams in Nova Scotia for use as fire-bricks, etc. Considering the importance of the steel industry to Nova Scotia and the many uses to which such bricks could be applied it would seem as if there was reason to pay more attention to this matter. The use of bricks and stone generally will, of course, increase as the timber resources of the province become depleted.

A chapter is devoted to a history of the agitation against the Truck System in Cape Breton, in the abolition of which the author states he was largely instrumental. Another chapter deals with the co-operative movement among the miners. This movement has had several severe setbacks in Cape Breton, but several successful societies are now doing business in the mining districts, and there seems really no adequate reason why the principles of co-operation should not consort as well with the genius of the Cape Breton miner as they have with that of the miner in other countries, notably in England. The secret of the failure of many of the co-operative societies in the past in Nova Scotia appears to have been that they did not do business on a strictly cash basis.

There are several interesting chapters in the work on the iron industries of the province, but your correspondent's knowledge of this matter is too limited to enable comment thereon.

ONTARIO.

Cobalt.—Navigation has now been open on the Montreal River for some little time, and boats are running between Latchford and Elk Lake. The two navigation companies that were operating on this route last year have been merged into one company. At the beginning of the season a good deal of trouble was experienced at first on account of several of the boats being put out of commission on the initial trips, but they have now been put into service again. For the present only one trip a day is being made, but when the traffic warrants it two trips each way will be made daily.

The Kerr Lake people are optimistic regarding the Wettlaufer property in South Lorrain, which they have acquired. The development work being carried out is giving excellent results, so much so that the management will considerably extend the scope of their operations. When the new twelve-drill compressor is running, the cost of mining will be greatly reduced. It is expected that this mine will shortly become a regular shipper. The Keeley now has its plant running, and will carry on the work of opening up its property as rapidly as possible. At the Maidens property the shaft on the No. 2 vein is down about sixty feet, but the vein was dipped from working. Sinking will be continued for some distance farther before a crosscut is run to cut the ore body. The vein in the shaft carried good values in native silver. The Mines Power Company contemplates installing a compressor of about fifteen drills capacity, somewhere in this district, in order to help out some of the smaller properties until they are in a position to install machines of their own. Five silver bricks, valued at between four and five hundred dollars, were found a short time ago on the Princess property. The silver had evidently been stolen, and had been hidden for some time. So far no owner for them has appeared.

Since the last statement of shipments from the Gow Ganda camp was given out, the Millerett, formerly known as the Blackburn, has shipped another car of high-grade ore. This makes a total output from the district for the year of about 325 tons, and from the Montreal River district as a whole, 345 tons. All of this output was high-grade ore, none of which ran less than 1,000 ounces of silver to the ton. On the Rawhide property, near Shanty Lake, a discovery is stated to have been made in a winze about 35 feet from the tunnel entrance. The Temiscaming and Hudson Bay Company, in the same vicinity, are working the McAlpine claims and good results are reported. A small steam plant was installed just before the break-up. A shaft is now down about twenty feet, and there is about two inches of high-grade vein matter. The country rock is also plentifully shot through with leaf silver.

The Cobalt Lake Mine seems to be coming into its own at last, and never in the history of the property have the physical conditions been so satisfactory. In sinking the winze to the 280-foot level, another rich vein has been encountered. This makes the third high-grade vein that has been discovered in the past few months. The new ore body is several feet wide and running through it are several stringers of high-grade ore. The rock between these stringers also carries leaf silver and argentite. Shipments are now being made more or less regularly and it is probable that they will be considerably increased in the near future.

The German American Company, in South Lorrain, has decided to put in a steam plant during the summer to open up a big calcite vein on the property. A shaft has already been sunk 50 feet by hand, and this will be continued another 50 feet. The vein is calcite with some smaltite and low assays in silver. On the Harris Lorrain, which adjoins the Frontier property, a force of 30 men has been started prospecting. A small plant will be installed. Another plant is to be put in on the adjoining property known as the Wendie, where twenty men are already trenching the surface. The opening of navigation has been responsible for the renewed activity of this district, which is growing in importance every day. During the summer, considerable road building, which is very badly needed, will be done. The government has made a small grant to assist in this work.

The O'Brien has made another shipment of silver bullion to the Bank of England. The bars contained 18,250 ounces of fine silver, valued at $9,675.

The Silver Cliff mill is now being operated with electricity supplied by the Mines Power Company, and the returns have been very satisfactory. It is, however, only being run to about half its capacity at the present time, as some of the motors installed were found to be too light for the duty required. As soon as the new motors are in the production will be much increased.

It is stated that the Cobalt Central is to issue between $300,000 and $400,000 worth of bonds. This will clear off their present indebtedness, and provide working capital for the future. The property is evidently suffering from too much New York mismanagement. The mine is in good shape, and there is several months' run of mill rock broken in the stopes. For the present all the miners have been laid off and only enough men are employed underground to supply the broken ore for the mill. The Bailey property adjoining has contracted for a mill run of 500 tons, and a small tonnage of the concentrating dump of the Crown Reserve is also to be treated at the Cobalt Central.

Blackburn and Jones, the men who were responsible for the fake rush into the Caribou Lake district, have fallen into the hands of the police. They have already come up for preliminary hearing ,and have been committed to North Bay to stand trial.

One of the most interesting annual reports issued this year is that from the Nipissing Mining Company. This is the most favourable report yet issued, and shows an excellent state of affairs on the property. During the last year the net earnings were increased by $775,000; the dividend payments were increased $660,000; and the surplus increase was over $100,000.

The value of cash on hand and ore on hand, in transit, and at the smelters increased $400,000. The cost of producing silver was decreased from 20.7 cents to 16.39 cents per ounce. A total of $1,500,000 was paid out in dividends. The ore reserves are now estimated at 6,538,000 ounces, valued at $3,269,000. The reserves are, it is altogether likely, much greater than this, for when a vein is opened up by a drift without any raises or winzes, only ten feet of ore is allowed above and below the drift. At the beginning of the year the reserves were estimated at 2,156,000 ounces, and after producing 4,646,876 ounces, they were estimated at the end of the year at 6,538,000 ounces. The total production up to date has been 12,747,467 ounces. The gross profit on production for the year was $1,687,228. During that time 33 miles of trenches were dug at a cost of $806 per mile, the average depth being 3.4 feet. The report states that this is the most economical and satisfactory method of prospecting, but goes on to say that the management cannot hope to discover all the veins, unless all the overburden is removed. Plans are under way for carrying this out. A new vein was recently discovered, running parallel to No. 101 in the crosscut between the Meyer and Fourth of July shafts, at a depth of 75 feet.

The mine owners of Gow Ganda have petitioned the provincial government to construct a road that will connect that district with some outside point that has railroad transportation. They also urge the construction of a branch line from the T. & N. O. Railway. There is no possibility of such a line being built for some time to come, but the government has appropriated the sum of $30,000 to construct a wagon road from Charlton to Elk Lake. This will connect with the present road from the latter to Gow Ganda, and will aid materially in providing transportation facilities to the district. The lack of this has been the greatest drawback with which the new camp has had to contend and operators in that section feel that some action should have been taken long ago. The shipments from the district, which aggregated about 325 tons of high-grade ore, were greater than was expected, and the mining men point to these as a reason for government aid.

The shaft of the Agaunico property is being sunk from the 250 to the 300-foot level. It is stated that Huronian slates were encountered at a depth of 250 feet, and as these slates have been found to be very productive in this camp, the management will continue sinking in the hopes of opening up an ore body. Work was originally started on one of the largest cobalt veins in the district, but although they have the cobalt at depth, the silver contents are, as they always have been, very low.

A vein has been cut in the Tretheway Mine about 140 feet from the No. 2 shaft. The vein was opened up on the 65-foot level, and shows several inches of high-grade ore. The new concentrator is about completed, and will it is expected, start running in a few days. The new shaft near the Hudson Bay boundary line is all timbered, and in a short time the company will proceed to open up the veins discovered in that section.

A decided improvement has lately taken place in the La Rose properties, good ore bodies having been opened up on the Lawson, Princess and main La Rose workings. At the Lawson, a drift was run from the 88-foot level on the "Keewatin" vein. There is now between three and four inches of high-grade ore showing in the drift. This is practically the first important ore shoot opened up at any depth . The greatest development has, however, taken place in the main La Rose workings, where several veins have been proved to greater depths. There are now three veins on the Princess that are producing good ore, and in the near future some of the outlying claims are to be opened up. At the recent annual meeting of the Nipissing, Mr. D. Lorne McGibbon, the president of the La Rose, was elected a director of the former company. This would seem to point still more plainly to the amalgamation of these two properties. Mr. McGibbon has for some time, been entirely favourable to such a scheme, although there are, however, many difficulties to be overcome before its culmination can be expected.

The Hargraves Mining Company has been notified that its petition to have the royalty reduced from twenty-five per cent. of the gross proceeds to twenty-five per cent. of the net profits, has been granted by the government. It was not generally known that this company had been trying for the royalty reduction, and with the exception of the Chambers-Ferland, it is the only one to get it direct from the Government. All the other companies that got the reduction, paid to the T. & N. O. Railway Commission. The policy of the government seems to be to collect the heavy royalties as long as the companies can manage to stagger along and still pay them, but where the company can no longer do that, then there is a chance of getting them reduced.

The Crown Reserve is having a hundred tons of the dump run through the Cobalt Central mill, in order to get an idea of its value. If the returns are favourable, it is possible that it may build a concentrator for itself. Its concentrating dump is estimated to contain approximately 25,000 tons and it is adding to it at the rate of about fifty tons a day.

At the Provincial Mine, which was bought from the government at the last sale of Gillies Limit lots, a good vein was encountered while sinking the shaft near the boundary of the Savage property. The vein was cut at a depth of 80 feet and shows about four inches of high-grade ore. It dipped from the shaft a few feet lower down, however, and a crosscut will be run from the 100-foot level to intercept it.

Several companies have lately commenced operations in the Gillies Limit, but so far the main operations are confined to trenching. At the Wyandoh, good ore is being found in the drifts at the 110-foot level. This is on the same vein that is being worked on the Waldman property adjoining.

The new machine shop of the Tretheway has been burned down. This will in all probability, somewhat delay operations in the concentrator, as a good many of the machine parts were being made on the property.

Porcupine.—The government has given notice that upon all claims staked in the Porcupine district, between the first of January and March fifteenth, the time for doing the assessment work, will be extended to June the fifteenth. This concession was made on account of the petitions asking for it, that gave as the reason the exceptionally early break-up, which practically disorganized operations in that section. Gasoline launches are now running and are proving to be a material aid in the transportation problem. A good summer road is, however, badly needed, and although several starts have been made, nothing of any importance has as yet been accomplished. Government aid is much needed in this undertaking, and the district as a whole will naturally suffer until it has been built. Although no official statement has as yet been given out, it is commonly reported that the returns from the car of ore shipped from the Timmins' property assayed in the neighbourhood of $200 per ton. It is, however, too much to expect that this will represent an average of the vein, and the owners will doubtless be well pleased if they get an average of one-tenth of that amount. That they are well satisfied with their original investment is, however, evidenced by the large holdings they have acquired, as it is stated that they have purchased and have under option about forty claims.

GENERAL MINING NEWS.

NOVA SCOTIA.

Springhill Mines, May 5th.—Vice-President E. S. McCollough, of the U. M. W., who has been expected here since the settlement of the Glace Bay strike, arrived to-night, and was accorded a grand welcome. He addressed a public meeting held in the Drill Hall. Mr. McCollough referred to the satisfactory settlement of the difficulties in Glace Bay, but further said that the settlement in Cape Breton did not mean a conclusion of the labour disputes here. The strike here was called independent of Glace Bay and could only come to a conclusion when the matters in dispute were satisfactorily settled to all concerned.

He praised the miners of Nova Scotia for the splendid way they had conducted themselves during the strike, and told the men of Springhill that they would now receive more attention. The U. M. W. had spent over a million dollars in Nova Scotia since the strike commenced, and they were prepared to spend more, and that the Union would stand by the miners of Springhill until the whole affair was settled right.

New Glasgow.—A rich strike of gold has been made on one of the veins of the Egerton property, Fifteen Mile stream, Halifax County. Reports affirm that four feet of mill stuff has been exposed for eighty feet, carrying high values.

ONTARIO.

Port Arthur.—The Atikokan Iron Company's blast furnace will be put in commission in a few days. Coal for the coke ovens has already arrived.

Cobalt.—The blacksmith and machine shops of the Tretheway mine were destroyed by fire on May 4th.

Gowganda.—The following petition has been sent to the Hon. Frank Cochrane, Minister of Mines, by the mine operators of Gow Ganda:

"The petition of the undersigned mine-owners in the vicinity of the Gow Ganda townsite, humbly sheweth:

"1. That the amount and value of the ore already shipped, together with the amount in sight, additional mining machinery now being installed, and other actual development work, fully establishes the fact that this is a genuine and established mining camp of large extent and rich values.

"2. That owing to the lack of roads and other transportation facilities the growth and development of the camp is greatly handicapped and investment discouraged.

"3. That your petitioners feel that these facts will warrant your department taking into serious consideration the further extension of roads and transportation facilities.

"4. That particularly your department may see fit to take steps to shorten the road from Miller Lake by way of the present working mines, and to continue a government road westward across the east branch of the Montreal River to connect with or continue the Bisco road to the Wapoose River or other convenient point on the west branch of the Montreal River, thus giving highway facilities at all seasons of the year to the working mines and mine-owners on the west side of Gow Ganda Lake and across to the townsite.

"5. Your petitioners would further urge the early and immediate construction of a railroad, either by the government or by the granting of a charter to some company willing to undertake construction."

Dryden.—At the Detola mine the foundation for the stamp mill is just about finished and trips will shortly be made to the Glass Reef property for balance of the mill machinery which was unable to be brought on the ice owing to the early breakup.

BRITISH COLUMBIA.

Portland Canal.—The Big Casino group of claims in the camp has been sold to a Vancouver syndicate. The transaction was put through by the Mercantile Trust Company.

Stewart, May 3rd.—One of the largest companies so far incorporated to operate in the Portland Canal is that of the Roosevelt Mining Company, Limited, with headquarters in Vancouver. This undertaking has been formed to acquire the interests of D. J. Rainey and Graham Chambers in the Roosevelt group of five claims located on Bitter Creek, for which surveys have been made and applications for crown grant are now pending. The provisional board of directors has the names of Joseph Chew, lumber manufacturer of Vancouver; A. R. Davis, of the same city, and D. J. Rainey, of Stewart. Other names will be added after the preliminary meeting of the directors.

The Roosevelt group is among the oldest located in the camp and has a considerable amount of development work in tunnels and surface cuts.

Nelson.—News of much activity comes in from the Slocan, where with the opening up of spring, mining operations are general. At the Standard mine at Four Mile Creek, near Silverton, a silver-lead proposition, some fine leads have been struck, and it is estimated there is enough ore in sight to keep a crew of twenty men stoping it out for five years. The Standard, which is owned principally in Spokane, has been working for the past five years, but the present strike has been made in recent weeks. G. H. Aylard, New Denver, is manager.

The Van Roi mine at Silverton, one of the biggest silver mines in West Kootenay, has a force of 100 men at work getting out ore, besides a crew of five men on a diamond drill. Some very fine cores have come from the diamond drill, which indicates an abundance of ore in the leads now being worked, as well as in several parts of the area surrounding the workings. The Van Roi mine, owned by a company in the Old Country, promises to be one of the largest silver producers in the province. The manager is Douglas Lay.

Nelson.—Confirmation of the recently-reported strike on the Rossland War Eagle, of an entirely new ore body of high-grade ore ,has been made. The importance of the discovery has been rather under than over-estimated. The shipments are said to average $40 per ton in gold and about five per cent. copper, a much higher average for similar tonnage shipped in one bonanza production this year. The Le Roi hopes to attain similar results and is pushing its diamond drill work as fast as possible.

At the annual meeting here of the Nugget Gold Mines, Limited, operating at Sheep Creek, the old directors were elected and the report presented was decidedly satisfactory, showing solid financial management and excellent indications of a successful year at the mine. Last year 5,000 tons were milled, producing $78,860. The concentrates averaged $5,200 at the smelter. There are no developments of the strike among the British Columbia Copper Company at Mermon. The company has given the men until to-day to return to work.

Vancouver.—On the McLennan property, Moresby Island, a stamp-mill is being erected. The machinery was shipped early in April.

YUKON.

Dawson, April 28th.—The Canadian Klondike Company's dredge No. 1 started operations yesterday for the season, the earliest in the history of the camp. The company expects to operate 200 days before cold weather compels a shutdown.

The season here is more backward than was expected three weeks ago. A spurt of warm weather then laid the trails bare. It has since been very cold at nights, with the temperature moderating slowly. The real thaw has now begun and water is running freely. Ten inches of snow fell several days ago, which

means great benefit to the miners for hydraulic sluicing purposes.

Dawson, April 30th.—The striking of quartz claims continues one of the popular enterprises. Everywhere throughout the camp men are showing their faith by the planting of stakes, and not a few in the undertaking of actual development work.

Some of the most extensive staking of late has been done on Sulphur, Gold Bottom and Meadow Creeks by A. A. Knorr and associates. The staking on Sulphur is on both limits of the creek and extending on the right limit well over toward Parker Creek, a tributary of Indian River.

Forty-one grants for quartz claims were issued at the gold office to-day.

One group of five claims was staked recently on the right limit of Bonanza, opposite Victoria gulch, by Paul Guite and others.

MINING NEWS OF THE WORLD.

EUROPE.

Hungary.

A system of wholesale theft has been brought to light at the Twelve Apostles gold mine at Brad, near Arad, in Hungary. The mine is the property of Count d'Harcourt de Gotha, and it is now known that the thefts of ingots and gold dust have been carried on for years, their extent being estimated at many million kronen. The thieves, it is alleged, formed a perfectly-organized band, recruited from among the workmen and officials, and under the direction of the local priest. The stolen gold was removed in various ways, often in emptied dynamite cartridge cases, and the amount of the plunder may be gained from the fact brought to light during the investigations that one of the workmen had recently been able to make a purchase to the extent of 70,000 kronen, while a gendarme had 80,000 kronen in a savings bank.

SOUTH AFRICA.

Johannesburg, April 16th.—The aggregate ore reserves at present developed by the mines of the Rand are valued by the latest estimate at £100,000,000, showing a profit on the basis of the present working costs of at least £40,000,000.

Profits on operations on the East Rand Proprietary Company's mines during March of this year are reported at £107,046. For March, 1909, the profits were £106,113.

MEXICO.

City of Mexico, April 29th.—The Real del Monte and Pachuca Company is reported to be confronted with the necessity of developing extensive ore reserves in the Real del Monte mines at Pachuca, due to the fact that up to this time the development work has been kept but little ahead of the mill requirements. The available ore supplies are diminishing, and the company's cyanide plants have ceased to operate at full capacity. Officers of the United States Smelting, Refining and Mining Company, which controls the Real del Monte enterprise, recently visited the mines, and the question of extensive development was gone into thoroughly with the general manager, C. W. Van Law. The Real del Monte controls more than seventy mines and at the present time only a few are being operated.

Chihuahua, May 4th.—M. F. Crosette, manager of the Promontorio silver mine for the Cusi Mining Company, of Chicago, states that when he gets the smelter returns for ore shipments made last month, his company will have received the purchase price of the mine, all development work, cost of machinery and every other expense. The mine was purchased in July, 1909.

UNITED STATES.

Washington, D.C., May 3rd.—The senate yesterday amended and passed a bill which already had passed the house to create a bureau of mines in the interior department. In addition to carrying on a part of the mining work heretofore done by the Geological Survey, the bureau will investigate the causes of mine explosions.

Mr. Root opposed the bill on the ground that the measure was a step "toward the usurpation by the national government of duties which belonged to the states."

"I believe we have enough to do," he added, "in performing the functions conferred on the national government, and should not take upon ourselves duties not incumbent upon us."

Mr. Guggenheim predicted that from $50,000,000 to $100,000,000 would be saved annually by the legislation and said the people of the United States had much to learn regarding metallurgy.

To show the importance of the mining industry, Mr. Nixon said that the mines supplied over 60 per cent. of the freight carried by the transportation companies of the country.

The bill places the bureau in the hands of a director, with a salary of $6,000 a year.

A portion of the work of the Geological Survey is to be transferred to the new bureau.

Goldfield, Nev., May 2nd.—Checks for dividend No. 7, payable to stockholders of the Consolidated Mines Company on April 30th, have been mailed from the company's office in Goldfield, and are accompanied by a statement setting forth the financial status of the company and showing that it is in a prosperous condition. The dividend is for 50 cents a share, being the company's regular dividend of 30 cents a share, together with an extra dividend of 20 cents a share, declared at the last quarterly meeting of directors. This payment involves the distribution of approximately $1,780,000 and brings the total of profits divided among shareholders to the sum of $7,468,348.

Birmingham, Ala., May 5th.—A report was received here late this afternoon that 150 miners had been entombed by a mine explosion in a coal mine near Palos, Ala.

The chief State Inspector and First Aid to Injured Society members are flocking to the place. A special train is now leaving Birmingham for the scene.

Palos is a hamlet in Jefferson County, 30 miles from here, and there is no direct communication.

COMPANY NOTES.

PETERSON LAKE SILVER COBALT MINING COMPANY—PRESIDENT'S REPORT.

To the Shareholders of the Peterson Lake Silver Cobalt Mining Company, Limited:

Gentlemen,—In presenting herewith the fourth annual report of your company for your consideration, I must congratulate you upon the improved condition of the company, both from a financial and physical standpoint as shown by the reports of the treasurer and consulting engineer, and also upon the successful issue of your action against the former management which resulted in the payment into the treasury of the company of $53,000 cash and 160,000 shares of stock.

The consulting engineer's report shows that 111.32 tons of ore was shipped, netting $11,312.92 in royalty.

The Bank balance is $47,237.42, as against $6,818.35 at the end of the last fiscal year.

The issued capital has been decreased by 160,000 shares and now stands at 2,401,820 shares, and the stock in the treasury has been increased by a like amount.

The physical condition of the Little Nipissing lease has been much improved during the past year and one other of the leasing companies has made a discovery of value which seems likely to lead to shipping ore.

Two complete power plants have been added to those already on your property.

The company has for some time been developing a vein on unleased land, which appears to be a continuation of the producing vein on the Little Nipissing and your management look forward with confidence to developing shipping ore on their own ground within a short time.

Power is now being supplied to the various lessees by the public power companies and with the advent of this cheap power it seems certain that the profits this coming year will be much greater than the past and that many new discoveries will be made on your property.

(Sgd.) A. F. McLAREN.

SECRETARY-TREASURER'S REPORT.

Issued capital, 2,401,820; treasury, 598.180 shares; authorized, 3,000,000.

Balance Sheet.

April 30th, 1910.

Assets.		
Bank of Hamilton Current Account		$ 2,237.42
Bank of Hamilton Savings Account		45,000.00
Accounts Receivable		3,585.67
Plant, Machinery and Buildings		2,917.31
Mining Properties		2,510,216.25
Road Allowance Patent		49.75
Commission on Stock Sold		5,532.00
Discount on Shares		30,910.00
Development Account, including		
Estimated value of ore on hand, April 30th, 1909.	$38,717.19	
Add Consulting Engineering, Interest, Travelling, Mine and Management Expenses, including Island development for year ending April 30th, 1910	8,800.10	
	$47,517.29

To Shareholders—		
Recoveries, Suit, Peterson Lake vs. J. A. Jacobs, Edward and D. M. Steindler, Cash	$ 52,999.99	
Stock	160,000.00	
	$212,999.99	
Deduct Expenses	12,056.96	
		200,943.03
Capital Stock (authorized $3,000,000)		2,401,820.00
		$2,634,761.74

To the Shareholders, the Peterson Lake Silver Cobalt Mining Company, Limited:

Gentlemen,—We have audited the books and accounts of your company for the year ending April 30th, 1010. In our opinion the above Balance Sheet is properly drawn up so as to exhibit a true and correct view of the corporation's affairs, as shown by the books on the closing date.

All our requirements as auditors have been complied with.

(Sgd.) J. L. Thorne Audit & System Company, Auditors.

CONSULTING ENGINEERS REPORT.

Toronto, May 1st, 1910.

The President and Directors, Peterson Lake Silver Cobalt Mining Company, Limited:

Gentlemen,—I herewith submit report of operations upon your property from May 1st, 1909, to April 1st, 1910. The figures for ore shipment cover the last twelve months.

Shipments for year.	Tons.	Oz. paid for.	Value Rec'd.	Royalty
Nova Scotia	67.157	56782.22	$29,052.68	$7,263.16
Little Nipissing	44.160	30883.40	17,045.63	4,011.41
Total, Silver	111.32	87665.62	$46,098.31	$11,274.57
Cobalt				38.35
Total Royalties				$11,312.92

Development.

During the past year the leases, with one exception, have confined their work principally to underground development, the Cobalt Leasors having done a considerable amount of trenching and diamond drilling.

The underground work accomplished by the different leases during the past eleven months was, approximately, as follows:

	Sinking and Raising.	Drifting and Crosscutting.
Gould Consolidated	28	53
Kerry Mining Co.	96	1171
Little Nipissing Mining Co.	70	868
Nova Scotia Mining Co.	110	278
St. Anthony Mining Co.	111	50
Union Pacific Mining Co.	35	...
Susquehanna Mining Co.	120	858
	570	3278

Cobalt Leasors Co., 530, diamond drilling; 1015, trenching.

The following table gives approximately the total amount of work done by each lessee up to April 1st, 1910:

Name of Company.	Acreage.	Diamond Drilling.	Trenching.	Raising and Sinking	Drifting and Cross-cutting,
Susquehanna Mg. Co.....	12	375	550	200	858
Kerry Mining Co.....	42	691	12200	472	1510
Little Nipissing Mg. Co...	15	...	500	345	1900
Nova Scotia Mg. Co.....	30	...	...	185	1208
St. Anthony Mg. Co.....	14	280	640	200	50
Union Pacific Mg. Co.....	10	...	450	148	15
Gould Consolidated Co....	23	...	1630	200	230
Cobalt Leasors Mg. Co....9.8		1113	3350	10	...

In addition to the development work done as above, the Susquehanna and Kerry Mining Companies have complete new power plants, and the Little Nipissing, St. Anthony and Union Pacific Companies have each expended a considerable amount of money in buildings and in additions to machinery and plant.

You will notice that the lessees that have done the most work are the Nova Scotia Company, the Kerry Mining Company, the Little Nipissing Company and the Susquehanna Mining Company, and of these the first three have got silver values. On the disputed ground adjoining the Nova Scotia lease, as also on the leased ground, there is a considerable quantity of rich silver ore blocked out ready for extraction. The Little Nipissing Company has joined the list of shippers of high-grade ore and promises well for the future, and the Kerry Mining Company, after a good many disappointments, has found good silver ore on the 200-foot level, which, when further developed, will possibly produce shipping ore in quantities.

In March a contract was let for sinking a shaft 150 feet from an island in the lake, and it is already down 35 feet, and has a strong 4-inch vein of calcite in the bottom. As this vein is about in line between, and on the line of strike of the Little Nipissing vein and the Nova Scotia vein, there is good reason to hope that valuable ore will be found in it.

Altogether the prospects for the future of Peterson Lake are much brighter than in the past. Owing to the much-delayed installation of electric power and air power the development work has been postponed from month to month, but now that power is available more vigorous development is promised.

I am,

Yours faithfully,

(Sgd.) J. W. ASTLEY.

COMPANY NOTES.

The directors of Bell's Asbestos Company, Limited, recommend a balance dividend of 1s. 6d. per share, making a total distribution of 12½ per cent. for the fiscal year. The amount to be carried forward is £14,168 9s. 4d. The usual bonus of 2½ per cent. has been dropped. This is attributed to the slack condition of the building trades.

STATISTICS AND RETURNS

RHODESIAN GOLD OUTPUT.

The total output of gold from Rhodesia for the month of March is cabled at 54,277 ounces, valued at £228,385, as against 48,443 ounces, valued at £203,888, in the previous month. This is an increase on the month of £24,497. There were 188 gold producers last month. The output of other minerals for last month was:Silver, 18,267 ounces; lead, 56 tons; coal, 12,272 tons; copper, 8 tons; chrome ore, 1,714 tons.

According to a Treasury return, issued April 20th, the total quantity of coal exported from the ports of the United Kingdom in 1909 amounted to 63,076,799 tons. The details show that the prices were as follows: Not exceeding 5s. per ton, 964,553 tons; exceeding 5s. to not exceeding 6s., 1,726,844; exceeding 6s. to not exceeding 7s., 2,162,768; exceeding 7s. to not exceeding 8s., 2,440,857; exceeding 8s. to not exceeding 9s., 9,500,552; exceeding 9s. to not exceeding 10s., 11,800,963; exceeding 10s. to not exceeding 11s., 8,041,973; exceeding 11s. to not exceeding 12s., 4,352,212; exceeding 12s. to not exceeding 13s., 4,258,478; exceeding 13s. to not exceeding 14s., 6,987,120; exceeding 14s. to not exceeding 15s., 5,226,273; exceeding 15s. to not exceeding 16s., 2,061.889; exceeding 16s. per ton, 3,553,317 tons.

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending April 22nd, and those from January 1st, 1910, to date:

	April 22. Ore in lbs.	Since Jan. 1. Ore in lbs.
Buffalo	58,900	644,078
Chambers-Ferland	41,950	164,250
Coniagas	78,000	512,096
Crown Reserve	200,700	1,792,070

NOTICE

STUDENTS EMPLOYMENT REGISTER,

The CANADIAN MINING JOURNAL has opened an employment register for students taking mining or metallurgical courses at Canadian Universities or Technical Colleges. Mine operators who wish to employ students during the summer months are requested to communicate with the Business Manager.

Students are requested to send in their names, along with brief records of experience. These will be filed and no effort will be spared on our part to place applicants in immediate communication with possible employers.

Save 50% of the Power

by using NISSEN STAMPS

Descriptive Pamphlets on request

Owing to the great crushing efficiency secured the power required to operate Nissen Stamp Mills is about half that of other mills of the same capacity output.

One user writes :—

THE CANADIAN FAIRBANKS CO., TORONTO, ONT.

Dear Sirs,

In answer to your inquiry regarding the Nissen Stamps supplied by your firm. These stamps are running steadily on some of the hardest rock on the Continent, they are crushing 5.3 tons of ore per head in twenty-four hours. The feed rolled down to go through about a one inch hole.

The screen used for the above tonnage was 30 x 30 mesh, 28 gauge wire, opening .018. With a coarser screen the tonnage would of course be larger.

The shoes and dies wear even, and the splash is well distributed over the screen.

The arrangements for keeping up the weight of the stamps are very good.

I can recommend the Stamps. Yours truly.

(Sgd.) F. J. Bourne, Superintendent.

STAUNCH AND RELIABLE

We build all sizes, suitable for PROSPECTING or PLEASURE.

Send for Catalogue.

THE PETERBOROUGH CANOE COMPANY, LIMITED.

PETERBOROUGH, ONTARIO.

This year we are building **Green Silk Tents** which we believe will be popular with Tent users. They are no heavier in weight but have an advantage over white color, for **sleeping purposes** so that one is not awakened by the early rising sun, and can sleep in comfort. All sizes at reasonable prices.

We are sole manufacturers of STANDARD WEATHERPROOF DUCK TENTS, Tarpaulins, etc. For Camp Beds, Chairs, Stoves, Grey Blankets or any other supplies. Send your orders to

J. J. TURNER & SONS, - Manufacturers,

Agents Everywhere PETERBOROUGH, ONT.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

GEOLOGICAL SURVEY

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, and with many local areas and special subjects.

MARITIME PROVINCES

The whole of Cape Breton, and a large portion of the coal and gold fields of Nova Scotia, have been reported upon, and mapped on a scale of 1 mile to 1 inch. The remaining portions of the Province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter Provinces, mapped on a scale of 4 miles to 1 inch.

QUEBEC

Quebec, south of the St. Lawrence, has been reported upon, and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the Province north of the St. Lawrence are also available.

ONTARIO

A large part of the Province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

THE PRAIRIE PROVINCES

Geological maps and reports have been issued covering the greater part of the Provinces of Manitoba, Saskatchewan, and Alberta.

BRITISH COLUMBIA

The southern portions of British Columbia, as well as other parts of the Province, have been reported upon and mapped.

YUKON

Many of the important areas in the Yukon have been reported upon and mapped.

THE NORTH WEST TERRITORIES

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of a report or map will be sent to Canadian applicants free of cost, and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

Applications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.

THE FOLLOWING GEOLOGICAL MAPS HAVE RECENTLY BEEN ISSUED:

CANADA

1084. General Geological Map of Canada. Scale 100 miles to 1 inch.

NOVA SCOTIA

1019. City of Halifax Sheet.
1025. Waverley Sheet.
1037. Windsor Sheet.

The above sheets belong to the regular series of Nova Scotia map sheets on a scale of 1 mile to 1 inch. The first includes Halifax City and Harbour, the second the Waverley Gold District, and the third Gypsum Quarries.

ONTARIO

1023. Geological Map showing position of Corundum-bearing rocks in Central Ontario.
1076. Gowganda Mining Division.

This map besides representing the geology of the Gowganda area, represents the geography of a considerable area to the east and north.

980. Portion of Algoma and Thunder Bay districts, Ontario, 1908. W. J. Wilson.
1081. Region lying north of Lake Superior between the Pic and Nepigon Rivers, Ontario, 1906. W. H. Collins.

BRITISH COLUMBIA

1002. Geological Sheet, Special Map of Rossland.

This map, on a scale of 400 feet to 1 inch, besides accurately indicating the topographical and cultural features, shows the geology and location of veins.

1004. Geological Sheet, Rossland Mining Camp. Scale 1200 feet to 1 inch.
1074. Sketch map of Sheep Creek Mining Camp, West Kootenay, B.C., scale 1 mile to 1 inch.

YUKON

1041. Geological and Topographical Map of Whitehorse Copper Belt. Scale 1 mile to 1 inch. Also several detail maps of same belt.

NOTE.—Maps recently published may be had on linen cloth, for use in the field, at 10c. per copy.

REPORTS

1072. Summary Report of the operations of the Geological Survey for year 1908.
1085. Descriptive Sketch of the Geology, and Economic Minerals of Canada. G. A. Young. Introduction, R. W. Brock.
1075. Gowganda Mining Division, 1908. W. H. Collins.
1035. Coal Fields of Manitoba, Saskatchewan, Alberta, and Eastern British Columbia, 1908. D. B. Dowling.
1050. Whitehorse Copper Belt, Yukon. R. G. McConnell.

NEW CATALOGUE

1073. Catalogue of Publication 1843—1909.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

MINING AND SCIENTIFIC PRESS

Established 1860

Controlled by T. A. RICKARD

Associate Editors Courtenay DeKalb, H. Foster Bain

For nearly half a century the

Mining and Scientific Press

published in the great western mining centre has recorded the developement of the metal mining regions. Beginning with the industry itself, it has told from week to week the fascinating story of the progress of mining practice. It is edited and controlled by mining engineers for mining engineers.

Published weekly at 667 Howard St., San Francisco, Cal.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are: Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows:

All mines belong to the Goverment of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unserveyed territory, is open to prospecting.

Miners' Certificates good for a calendar year may be obtained by sending $10.00 to the Department of Mines. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minium being 40 acres in unserveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of $10.00 plus a yearly rental of $1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed territory may be purchased as a mining concession at the price of $20.00 per acre if within 20 miles of a railway in a straight line, or $10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

The Hon. Minister of Colonization, Mines and Fisheries
Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

NOBEL GELIGNITE

It always breaks cleanly to the bottom of the drill holes and is free from fumes of any kind. Equal to 75% Dynamite and is sold at a price producing very much better results in terms of Rock Broken or Extracted and money spent.

"WINTER BRAND" DYNAMITE

Is only one strength, if anything, a little stronger than 50% Dynamite. **It does not freeze,** or rather, explodes with perfect efficiency when frozen **and needs no thawing.**

"AUTUMN BRAND" DYNAMITE

Is packed in all the usual percentages. The powder is similar in appearance, character and effect to ordinary Dynamite, except that the freezing temperature of the Nitro-Glycerine is reduced from 40° F to a little under 30° F.

PERMITTED EXPLOSIVES for Coal Mines
Nobel Monobel, Saxonite and Carbonite.

ELECTRIC HOISTS

FOR

MINING WORK

Electric Hoists, to give the best service, must be designed and built to meet operating conditions. The hoist shown in the illustration is operated by a 150 h.p. induction motor and designed for a load of 5,400 lbs. at a speed of 800 ft. per minute. We manufacture both mechanical and electrical parts of these hoists. Miners will find it to their advantage to place their orders with one firm and thereby avoid the delays and annoyances inevitable when responsibility for successful operation of the unit is divided.

Renold Patent Silent Chain

is constructed on sound, simple principles, and does not require expert knowledge to either install it or make a joint.

Spring Cushion Sprocket with Cover off.

For drives of a pulsating nature, Spring Cushion Sprockets are furnished, in which springs are interposed between the boss and the rim, thus absorbing the fluctuations of the load, preventing the shocks from being transmitted through the machinery. By their use chains are being successfully applied to drives of an extremely severe nature.

"CLEVELAND" STOPE DRILLS

EFFICIENCY:—Of course you want the stope drill which has the highest efficiency, but you must pick out the one that will have as high an efficiency a year from to-day. Isn't it true that your stope drills decrease steadily in efficiency as they grow older?

REPAIRS:—Repairs which must be made from time to time after the part has given long and satisfactory service, are not a source of dissatisfaction, but dont you find that your stope drills are constantly needing something new?

DRILLING CAPACITY:—As long as your stope drill will put in sufficient holes per shift to drill up your stope there is no argument in favor of your changing to our drill just because it will drill faster. We know that. But we know that the "CLEVELAND" Stope Drill will do as much work per shift when it is one year old as it will when one week old, and that is what you want, isn't it?

THE "CLEVELAND" Whether you purchase your stope drills after considering efficiency, repair cost, or drilling capacity, the "Cleveland" should be the stope drill you specify, for its design is such that the initial efficiency is the highest possible in an air tool, and the piston and valve action are so related that the "Cleveland" is just as efficient when it is a year old as when it is brand new; we **know**, and our information is gained from hundreds of installations that the "CLEVELAND" will cost less for repairs **per year** than any stope drill made; a 30 day trial will convince you that the "CLEVELAND" will drill as much per shift as any other stope drill, and we have machines always in stock ready to ship for trial if you will drop us a line, As you have everything to gain and nothing to lose, why not investigate NOW?

Rapid Sinking

of shafts or winzes depends on your drill's ability to keep the holes free from sludge.

This Pulling Power is found to an exceptional degree in Sullivan Drills; which means that in a given kind of rock, these drills are able to use a heavier blow and to cut more rock at a stroke than other types.

To put it in another way, Sullivan Drills are able to handle longer and heavier steels and to drill deeper holes than others of the same piston diameter.

These facts are constantly being verified in every-day practice. The details of valve motion and rotation which lie back of these advantages are described in Catalogue 660—May we send it?

Amatite ROOFING

NEEDS NO PAINTING

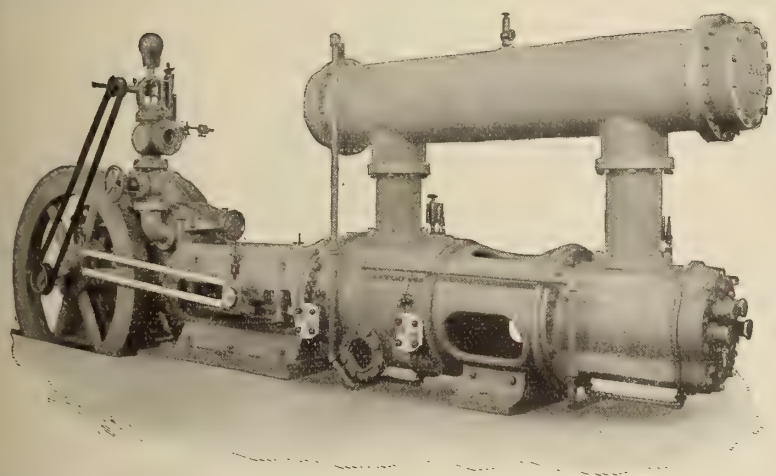
MOST ready roofings require special painting and coating, and unless this is done regularly, you are sure to have leaks and trouble right along.

If you use Amatite, nothing of the sort is required. You will have real roof protection *without painting* of any kind.

Amatite is made to stay waterproof and give protection year after year, without any thought or care on your part.

First—Because it is waterproofed with Coal Tar Pitch.

Second—Because it has a real Mineral Surface.



Amatite, owing to these features, is the most economical roofing made. Its first cost is low, and you are *saved* all future expense for repairs or paint because it will need neither.

If you haven't seen Amatite, write for a sample to-day. From it you will very quickly understand why it doesn't require painting; why it does not leak; and why it saves you money.

Address nearest office to-day.

CENTRIFUGAL PUMPS

Our pumps are distinguished by their ability to stand up under hard usage. They are built for it. Light and compact, their durability and efficiency under trying conditions has made them deservedly popular for Mine Drainage Work.

Built in sizes with discharge opening up to 14" in diameter. In Horizontal and Vertical Styles. For Pulley, Engine or Motor Drive.

Completely illustrated bulletin No. 200, sent on request.

The Waterous Engine Works Co., Limited,

BRANTFORD, - CANADA.

THE McLEOD TABLE

Has been **thoroughly developed by years** of continuous hard service in competition with the best. One of them has run 24 hours daily for over 5 years except ordinary mill stops and is still in use.

Construction entirely **Steel** and **Iron** except the deck.
Deck held firmly **Down** as well as **Up.**
Warping and Trembling—The curse of many other table decks—**Simply Impossible.**
Each leg a small jack screw, to set exact slope desired.
Legs spread to give broad, stable support. No tremble.
Sharp Stroke. Hand adjusted while table is in motion, and the result can be seen.
Holds the Line for a whole shift without fluctuation—that means constancy of results and fewer men employed. In recovery of values and durability it has no equal. A 1" Belt will run it.
Light Weight, gained by skillful design of parts, yet it is as firm as its foundation, weighs about half the tables you are familiar with, hence
Cuts Freight Bill in Two, putting about $15. to $30. in your pocket for each table bought.

PRICE RIGHT TOO.

For Sale at Public Auction

On June 9th, 1910.

That Gold Mining Property Situated at Harrigan Cove, County of Halifax, Nova Scotia, and known as

St. Anthony Gold Mine.

Owing to circumstances which rendered it necessary, it has been reluctantly decided to offer this well known Gold Mine, together with all the Buildings and Machinery situated thereon, at public auction.

The mine is situated at Harrigan Cove, in the County of Halifax, Nova Scotia, and comprises 192 mining areas, under lease from the Crown. Development work has been done on four of these areas only, on the St. Anthony lead so called. The returns from this lead **Produced $94,000.00 in 18 month's work; averaging about an ounce of gold to the ton.** The property also contains several other gold bearing quartz veins, varying from 18 inches to 8 feet in width, which have not yet been developed. Surface tests taken from some of the veins gave very promising results. Two of the tests gave better results than were obtained from the above mentioned **St. Anthony** lead when it was first opened up.

The following unsolicited testimony regarding this property is contained in Mr. E. R. Faribault's (of the Dominion Geological Survey Staff) report of the survey which he made of the district:—

> "Some very rich float has been found south of the Antecline, and several large belts of quartz veins have been cut in the 600 feet of strata between the Antecline and the St. Anthony lead. **Most of which are well mineralized and show gold.** None of them have, however, been cut in more than one or two places along their course, and they offer a **very compromising undeveloped field for the prospector.** The St. Anthony lead has so far proved the best producing lead of the district. This lead has been traced 1500 feet in length east of the present workings. **It may be said that the very large field of unemployed auriferous belts here present should draw the attention of the prospector and the St. Anthony property already proved productive is capable of being worked on a much larger scale."**

The Buildings and Machinery installed on the property comprise the following:—

1 20 Stamp & Steam Gold Crushing Mill with 10 stamps installed. 1 60 H. P. Engine with shaftings. Pulleys and belting complete. 1 80 H. P. Boiler. 1 Hoisting Engine. 1 Friction Hoist. 2 Silver plated Amalgam Plates. 1 Wilfley concentrating table. 1 Blake Rock Breaker. 1 Water Tank. 2 Bucket Pumps. 1 Steam Pumping Engine with hose. 1 Northey Steam Pump. 1 Upright Boiler and Engine. 1 Rand Steam Drill and Fittings. 3 Shaft Houses. 1 Blacksmith Shop. 1 Office Building. 1 Cook House with accommodation for 15 men. 1 Barn. 1 Barn Waggon. 1 Double Team. 1 Cart. Coal Shed. 1 Magazine Building. 1 Store house for supplies.

This property will be positively offered at Public Auction to the highest bidder in the Board of Trade Rooms at Halifax, N. S. on Thursday, June the 9th, 1910 at 11.30 o'clock a. m.

Terms of Sale,—Ten per cent. at time of sale, balance within Thirty days from date of sale.

Any intending bidder desiring further information can obtain the same by addressing The Secretary, St. Anthony Gold Mining Co., Limited, Box 201, Halifax, N. S.

PECK CARRIER

The Standard Machine for handling Cement, Crushed Rock, Hot and Cold Clinker, Coal, &c.

Horizontal Run of PECK CARRIER in Cement Mill.

IN our book describing this CARRIER we have included an explanation of the principles that govern correct construction and operation of conveying apparatus. Here is a quotation from page 16:

> "Don't use a CARRIER without crossrods between the chains: the weight of the buckets and load will cause the chains to tilt inwardly and the rollers will bear on the inside corner of the rails, instead of on the tread."

If your name is on our list you'll be sure to receive a copy; otherwise please notify us.

THE NEW FEDERAL COAL MINING REGULATIONS.

By an Order-in-Council, dated April 20th, 1910, certain significant changes are made in the Regulations for the disposal of coal-mining rights. The new Order-in-Council became effective on May 25th, 1910.

Under the new Regulations the term of lease shall be 21 years, renewable for a further term of 21 years, provided the lessee furnishes evidence, satisfactory to the Minister of the Interior, to show that he, the lessee, has complied in every respect with the conditions of the lease. As formerly the lease covered only 21 years, the change is desirable. Yet the question may fairly arise as to whether even 42 years is a sufficient period. Large investors may not think so. The surface equipment of collieries like, for instance, that of the Dominion Coal Company, represents millions of dollars. Each year sees additions to such capital expenditure. The life of a successful coal mine is long. Several of the collieries in the west possess sufficient reserves to predicate a possible life of 100 years. The Nova Scotian Government gave a 99-year lease to the Dominion Coal Company. Would it not be well for the Federal Government to follow this example? One particular aspect of this question is worth touching upon. Each lessee is permitted to acquire as much surface for mining operations as the Minister will grant him. Thus it is quite possible that a lessee, failing to obtain a renewal, may find himself at the end of 21 years in possession of surface rights and equipment but without any right to mine coal. If his surface rights cover the entry to the seams, a new lessee could obtain only the right to mine. In other words the property would be in a fair way to be tied up for all eternity.

The maximum area of a coal mining location is to be 2,560 acres, or four square miles. No person is allowed to hold more than one location. This regulation, of course, is easily evaded. The locator needs but to secure dummies. Hence the paragraph fails entirely of its object. In any case, four square miles is not an adequate area to provide for a coal mine. It would be far saner to fix the limit at from eight to twelve square miles.

The new Regulations provide that a person who has been granted a lease, and who subsequently abandons or assigns it, may, twelve months after the date of the lease, secure another location. This encourages the prospector. May it not, however, tend to restrict needlessly the activities of operating companies that wish to secure new locations?

Prospectors will appreciate the extension of time wherein applications must be filed. In cases where the location is distant more than 100 miles from the office

of a Government agent, the applicant is allowed, in addition to the regular 30 days, one day for each 10 miles, or fraction thereof, in excess of 100 miles. This will meet with warm approval.

One other paragraph calls for comment. Paragraph 13 provides that bona fide settlers shall be entitled to buy at the pit's mouth whatever coal they may require, but not for barter or sale, at a price not to exceed $1.75 per ton. Whilst the intention here is commendable, the wording is too vague. As the law does not specify the grade of coal to be supplied to settlers, the operator is permitted to palm off any kind of slack or culm. Moreover, fixing a definite price per ton is dangerous. Operating expenses are constantly increasing. The cost of coal at the pit's mouth may before long exceed $1.75. We would suggest that as all Dominion agents have free access to the books and accounts of coal mining companies, some effort be made to leave the adjusting of prices in their hands. In fairness to the operators it would be necessary to provide means of appeal and arbitration. It would also be essential to fix the price, not for an indefinite time, but for certain stated periods. We believe, however, that paternalism of this kind, it matters not how laudable the intention, is superfluous. The laws of supply and demand, and the rigours of competition, are the final adjusters of values. To set a fair price cumbersome machinery must be created and kept in motion. To fix an arbitrary price is unjust. Why, then, touch the matter at all!

Incidentally, we would like to have some light thrown upon the question as to what does or does not constitute a bona fide settler. We shall not be surprised if some difficulty is encountered in framing a satisfactory definition.

INDUSTRIAL FEDERATION.

The recently elected President of the Iron and Steel Institute in his opening address departed from precedent. Instead of touching upon matters scientific and technical, he reviewed the social and economic conditions that have obtained in Great Britain since the founding of the Institute, the year 1869.

The president, at the beginning of his paper, points out that while economics have become the recognized basis of politics, yet as the Institute is concerned solely with facts and not with inferences, he had no fear of trespassing upon the political field. His field is, therefore, confined to industrial and social aspects, to the entire exclusion of matters political. But whilst he draws comparisons between the industrial development of Great Britain and that of foreign countries, he makes no such comparison of social conditions, confining himself merely to marking the contrast in Great Britain itself as between the year 1869 and the present day.

On succeeding pages of the address it is shown that, although in the year 1869, Great Britain had an enormous lead over all other nations in the production of iron, steel, and coal, yet this superior position could not be maintained. "The output of coal, iron, a steel, the foundation of the national industry, cann in the nature of things, depend solely on the energy the workers and the ability of administrators. Ho ever rich in natural resources the soil may be, the e ment of area must always be a great factor in t case." Obvious as is the truth of this statement, it equally apparent that part at least of Germany's pr gress is due to something more than mere extent territory. And that something is what Great Brita has always lacked.

Forty years ago Great Britain was easily first in t production of pig-iron, coal, and steel. Now both t United States and Germany are far ahead of he Whilst Great Britain's position is still strong, a poi has been reached where purely physical conditions i dicate the future limits of industrial expansion. E pansion there will be for years yet; but not at anythi like the rate that is observable in larger countrie Comparisons with Germany and the United States a unfair. "We can only regain the position of supren acy that we occupied in 1869 by reckoning in with t United Kingdom our great dominions overseas." Thi we take it, is a constructive plea for imperial industri federation.

Touching the amelioration of social conditions i Great Britain since 1869, the broad statement is mad that since that year there has been a general advanc in money wages and a general decline in the prices o commodities. The wage-earner receives to-day 38 shi lings, where, in 1869, he received 20 shillings. To-da also, the worker is better housed, better fed, bette clad, and in all respects has a better chance in life.

The Presidential address makes cheerful reading The generalizations alluded to above are substantiate by means of statistics.

After reading it carefully, the impression is stron upon us that the British workman has surprisingl little to complain of.

THE LAST MINE MYTH.

Innumerable are the platitudes that have been writ ten concerning the credulity of man. More convincin than all the platitudes are the amazing instances fro real life. The latest and best test of blind belief is a project born in Boston.

Mr. J. Burpee Neily, not unknown to the inhabitant of Eastern Canada, is the president of the Vibora Mining Corporation, capital stock, $3,000,000; par value of shares, $5. Mr. C. P. Bowker is manager of the Viboras mine, which mine is situate eight miles from Hostotipaquillo, Mexico. But the Viboras is no ordinary mine. True, there is reported to be shipping ore running from $500 to $17,000 per ton. This, however, is so insignificant that Mr. Neily suggests counting upon only $100 per ton. And well can he afford this discount, for, within the mine lie 45 tons of silver and 29 tons of gold, hidden treasure that once belonged to

Spanish viceroy. So, at least, Mr. Charles P. Bowker ·lieves. The foundations of Bowker's faith are sug-·sted in the following paragraph—one gem in a scin-llating mass:—

"July 2.—Maximino has told me that there are some nine treasures in the Viboras, and I believe I have located them all with the twig, amounting to 45 tons of silver and 29 tons of gold, belonging to the last Spanish Viceroy and his family. . ."

Would we could quote more! We shall pause but to xplain that Maximino is a horrid person who takes it pon himself to be wise after the event. Whenever owker becomes discouraged, Maximino multiplies the easure by two or three and assures Bowker that it is ust a wee bit farther ahead. Hence Bowker is ever and gain on the point of striking the Spanish bullion. He isses, and Maximino shows him where he has been rong. Bowker has twigged the silver and gold. Far etter would it be for him to use that twig on Maxi-ino.

To those who appreciate the curious in literature e recommend this charming little study. Mr. Neily nd Mr. Bowker, with the assistance of Senor Maxi-ino, have Edgar Allen Poe skinned to death, frazzled o a finish, or even more so.

COMMENDATION.

The Mines Branch, it is announced, will presently ake up two urgent lines of work. It will investigate nd attempt to regulate the use of explosives. It will lso interest itself in the introduction of breathing pparatus for rescue work in coal mines.

Many months ago the CANADIAN MINING JOURNAL rged that the Mines Branch be directed to attack the roblem of life salvage in coal mines. The matter was rought up in the House of Commons by Mr. Claude lacdonell, one of the members for Toronto. The reply f the Hon. Mr. Templeman, though vague, indicated hat steps were to be taken at an early date.

The question of regulating the manufacture, stor-ge, and use of explosives was brought forcibly before he public through the recent disaster at Hull. But he matter was, some time ago, placed before the Mines Branch.

In both directions the Mines Branch should be cap-ble of accomplishing work for which the whole nation will be grateful. We have always had serious misgiv-ngs as to the advisability of Government officials un-dertaking research work of a more or less academic nature. One obvious objection is that such investiga-ions, important as they may be in the opinion of many, ake up time, money, and energy that should properly e devoted to just such problems as those mentioned bove.

The Mines Branch will win and will deserve our open nd hearty support if it gets down to business in regu-ating the use of explosives and in encouraging the ntroduction of rescue apparatus.

As illustrating the present position of affairs, we may instance the fact that after the recent explosion at Nanaimo, B.C., an officer of the United States Geological Survey had to be called on to instruct the men in the use of the Draeger apparatus. This should surely be unnecessary.

PREVENTABLE ACCIDENTS.

One of the most dangerous practices in mining is the habit of drilling or picking into old bottoms of drill-holes. These old bottoms, or "bootlegs," as they are labelled in the west, are due to the hole not breaking to bottom when it is blasted. Miners frequently take advantage of these old holes to start a new hole. If a residue of dynamite happens to remain in the "bootleg" there is a funeral. This fact, however, does not appear to discourage other searchers after short cuts to the future world.

During the session of 1909, the Ontario Government passed an amendment to the Mining Act forbidding drilling or the insertion of any metal tool into a hole that has been blasted. This, naturally, does not restrain the careless miner. But it furnishes to the mine manager the means of controlling and punishing his men. In fact, the Government can do no more than it has done. Upon mine managers devolves the duty of impressing upon their employees the criminality of taking foolish chances.

Incidentally, it must always be remembered that the "bootlegs" are evidence of bad mining.

EDITORIAL NOTES.

The peat producer-gas plant of the Department of Mines is now in daily operation. Visitors are invited to inspect the establishment.

It is satisfactory to learn that Cobalt ore shipments for the first four months of the year, notwithstanding the light shipments during January and part of February, are considerably larger than those reported for the corresponding period of 1909.

In the explosion in the Wellington colliery, White Haven, England, one hundred and thirty-seven miners lost their lives. Apparently the official warning, published all over Great Britain, to the effect that abnormally high barometric conditions rendered such explosions highly probable, was entirely disregarded. It seems that catastrophies are the only effective teachers.

Canada is to have a tungsten mining industry. The discovery of scheelite at Moose River, Nova Scotia, first described in these columns two years ago, is to be worked this summer. The ore is richer than most of the deposits worked at present. Many veins are exposed. The scheelite concentrates ideally, and, except for the presence of a small percentage of mispickel, will make an exceptionally clean shipping product.

THE CANADIAN IRON AND STEEL INDUSTRY.

By Watson Griffin.

III.

In previous articles I have outlined the difficulties that had to be surmounted in establishing the Canadian iron and steel industry, and described the plants at present in existence.

In considering the future prospects of iron and steel manufacture in Canada, the first factors to be taken into account are the character and extent of the raw materials, iron ore, limestone and fuel, their distance from each other and the means of transportation.

For purposes of comparison it may be well to outline the conditions that exist in the United States and the United Kingdom.

The first furnaces in the Pittsburg district were started on local ores, but now almost the entire supply comes from the mines in the vicinity of Lake Superior. James M. Swank, manager of the American Iron and Steel Association, says: "From the iron ore mines of Michigan and Minnesota to the coal of Pennsylvania the distance is 1,000 miles. Connellsville coke is taken 600 miles to the blast furnaces of Chicago and 750 miles to the blast furnaces of St. Louis. The average distance over which all the domestic iron consumed in the blast furnaces of the United States is transported is not less than 400 miles, and the average distance over which the fuel that is used to smelt it is transported not less than 200 miles."

The iron ore used in the Pittsburg district has to be brought from the mines of Northern Michigan and Minnesota by rail to a Lake Superior port, and there loaded on vessels, after which it must be carried through Lake Superior, the Sault Canal, Lake Huron, Lake St. Clair, the tortuous channel of the Detroit River, and finally through Lake Erie to Cleveland and other lake ports, where it is transferred to railways, again to be transported to the furnaces. This makes four handlings of the ore in transportation from the mines to the furnaces. When the iron and steel is made at Pittsburg it has to go by rail to Philadelphia, 354 miles; to New York, 445 miles; to Boston, 675 miles; to Buffalo, 270 miles. The distance from Pittsburg to Montreal is 710 miles by rail as compared with the cheap water route of about 726 miles from the works at Sydney, C.B., to Montreal.

The only blast furnaces of the United States that have their raw materials close together are in the Southern States. Of these the most favorably located are those of the Birmingham district, in Alabama, where fuel and ore are very close together. However, the Alabama furnaces are far from the leading markets both of the United States and other countries, and the freight rates on the pig iron and steel must be added to the cost of production. The nearest seaport is Mobile, 276 miles by rail from Birmingham, the centre of the iron district. It is 349 miles by rail from Birmingham to New Orleans, 448 miles to Savannah, 476 miles to Charleston, 766 miles to Newport News, 804 miles to Baltimore, 855 miles to Philadelphia, and 794 miles to Pittsburg.

The British blast furnaces at one time used only local ores, but now very large quantities of ore are imported. For many years British iron makers have been drawing ore supplies from Spain. In recent years ore has been imported quite extensively from the Gellivara district of Sweden, which is considerably north of the Arctic circle. The ore is carried by rail across Sweden and Norway to the Norwegian harbour of Ofoten, 130 miles north of the Arctic circle, where it is shipped to the British blast furnaces. The London Economist some years ago, discussing the probability of Great Britain losing supremacy in the manufacture of iron and steel, said: "It must be remarked for how long a period the mines in this country have been worked. The output of blackband ore in Scotland has been decreasing for years past and the greater portion of the pig iron now made in that district is from foreign ores. Cleveland, which has been one of the most prolific districts in the country, has now been worked nearly fifty years, and the best ore having been taken out we may soon have to fall back on the poorer, and consequently costlier kinds. It has been known for some time past that the best hematite ores in the Bilbao district in Northern Spain are fast deteriorating, and if we have to fall back on the poorer qualities, those containing a lower percentage of iron, they will be more costly, owing to the proportionately greater cost of carriage by sea."

From the standpoint of the iron-maker, Canada may be divided into four sections, the Maritime Provinces, Quebec and Ontario, the Northwest Provinces, and British Columbia. Economically Newfoundland should be included with the Canadian Maritime Provinces, Prince Edward Island, Nova Scotia and New Brunswick, but unfortunately Canadian statesmen have never realized the importance of bringing that great province into the Confederation.

Newfoundland's resources of coal and iron ore can only be guessed at, as only a very small part of the island has been explored for minerals. Very thin seams of coal have been discovered, but as yet none have been found of sufficient thickness to be of any value. In Conception Bay, about 35 miles from St. John's, there is an island about eight miles long and about two miles wide, known as Great Bell Island, on which are the extensive ore deposits belonging to the Dominion Iron & Steel Company, of Sydney, Cape Breton, and the Nova Scotia Steel & Coal Company, of Sydney Mines, Cape Breton. As shown in my last article, there is now no doubt that hundreds of millions of tons of good ore can be obtained from this source, and it can be laid down at the works at lower cost than ore can be placed at any blast furnace in Pennsylvania, while the coal and limestone are in Cape Breton within a few miles of the furnaces. It is quite probable that valuable iron ore deposits may yet be found on the Newfoundland mainland, but this is only conjecture.

Prince Edward Island is practically without mineral resource, although coal is believed to exist at a very great depth.

Nova Scotia is particularly well endowed with coal having extensive beds on both the eastern and western coasts of Cape Breton Island, in the central county of Pictou, and in Cumberland County at the northwest of the province. There are a number of seams of great thickness.

If all the iron ore in the province were concentrated at one point there would be enough of it to supply very extensive works. There are indications of iron in almost every part of Nova Scotia, and at one time it was commonly supposed that the province had almost inexhaustible supplies of this mineral. Investigation showed that most of the deposits were merely pockets, and

the impression became general that extensive bodies of ore would never be found in Nova Scotia. However, development work carried on in Annapolis County by the Canada Iron Corporation seems to indicate that the deposits there are very extensive. The Corporation owns and controls seven square miles of iron ore lands of Torbrook. The ore is a red hematite, and independent engineers have estimated the quantity obtainable as high as 300,000,000 tons. The Corporation has installed a plant at the mine having a daily capacity of 1,000 tons, and shipping facilities have been provided at Port Wade, N.S., with a dock-loading capacity of 2,000 tons per hour.

The Londonderry iron range in Colchester County extends for many miles and, although the deposits are not very deep, the total quantity of ore is believed to be quite large. As stated in my description of the Londonderry Iron & Mining Company's properties in a previous article, there are a number of varieties of ore in this range, including hematite, limonite, ankerite, siderite, and specular ores. The blast furnace of the Londonderry Iron & Mining Company at Acadia Mines is about midway between the coal fields of Pictou County and the mines at Springhill in Cumberland County.

There is some reason to believe that there is an extensive ore bed at Arisaig, on the coast of Antigonish County, but as no development work has been done this is uncertain.

Except in the case of some small pockets the iron ores of Nova Scotia are too high in phosphorus to make Bessemer pig iron. They are usually low in sulphur, but Nova Scotia coal is commonly somewhat high in sulphur.

Mr. J. E. Woodman, a mining engineer who has prepared a very interesting report on the iron ores of Nova Scotia for the Dominion Department of Mines, expresses the opinion that there are scattered throughout Nova Scotia in close proximity to transportation facilities by rail or water a large number of deposits which, while not individually extensive enough to justify the erection of local smelters, could be economically mined for transportation to smelting centres. He says: "It is even an open question whether it would pay existing smelting companies to buy them up. But if, instead, the individual owners were to develop them and contract for sale of the ore to the smelters, if necessary attempting an understanding with one of the smelting companies whereby the latter supplies the tools in instances in which the owner has no capital upon which to work, even under the present market conditions a number of the isolated deposits could be profitably opened up."

If the iron ore deposits at Arisaig should prove to be extensive, of good quality, and susceptible of being cheaply mined, the ore might be conveniently carried either to the coal of Pictou County or to the coal on the west coast of Cape Breton. It is possible that blast furnaces may yet be located in the vicinity of Pictou Harbour, using Pictou coal and drawing ore supplies from Pictou County, Arisaig and perhaps New Brunswick and Newfoundland.

Mr. J. E. Woodman suggests that Parrsboro, a port on the Basin of Minas, would be a favourable location for an iron and steel plant of large size. He says that ores could be conveniently brought to Parrsboro from the whole western Cobequid. Ore from the Torbrook and Clementsport mines in Annapolis County could be shipped by water to Parrsboro, while Londonderry ores could be brought there by a short rail haul. Brookfield, he says, is but eight miles from Truro, and with a Truro-Parrsboro railway the iron ore there would be within as easy reach of Parrsboro as of Acadia mines (Londonderry) to-day. The Hants County ores also could be taken to Parrsboro as easily as to Acadia mines. For flux limestone could be obtained from the vicinity of Windsor and anchorite could be brought from the Londonderry range. "Fuel," he says, "would come chiefly from Springhill, along the road over which most of the tonnage now goes, giving a short downgrade haul and avoiding the costly and roundabout freightage across the Cobequid Mountains, now necessary on the Intercolonial Railway. The road from Springhill mines to Parrsboro crosses the mountains by a very low pass, which involves no heavy grades. Should the buried western section of the Cumberland coal field be developed there would be one or more additional sources of fuel at close range."

The distance from the Springhill coal mines to Parrsboro by the railway referred to by Mr. Woodman is 27 miles. The distance by rail from the Torbrook iron mines to Port Wade, the shipping port, is 42 1-2 miles, while Port Wade is 77 miles by water from Parrsboro. If a short railway were constructed from Parrsboro to Truro, making connection there with the Intercolonial line to Stellarton, the coal field of Pictou County would be brought within a rail distance of about one hundred miles from Parrsboro. At present the railway distance from Stellarton to Parrsboro is 132 miles via Springhill Junction.

Iron and steel produced at Parrsboro could be conveniently distributed to all parts of Nova Scotia and New Brunswick. The distance by water from Parrsboro to St. John, N.B., is 82 miles.

It has also been suggested that the Torbrook ore might be smelted at Annapolis, to which coal or coke could be brought by water. The distance from Annapolis to Parrsboro is 87 miles. Works at either Parrsboro or Annapolis would have the advantage of not being absolutely dependent upon local raw materials as iron ore, coal and limestone could be brought by water from outside points in any emergency.

The greatest obstacle to the success of a large iron and steel plant dependent upon coal supplies from Springhill is the great frequency of coal miners' strikes in that district. If some permanent basis of settlement for labour disputes could be arrived at which would prevent strikes and assure continuous operation of the mines it would do much to promote industrial development in Nova Scotia.

The coal seams of New Brunswick so far as known are not thick enough to be of much value.

There are indications of iron in many parts of New Brunswick, but the only extensive deposits so far discovered are those of the Canada Iron Corporation in the Drummond iron range near Bathurst, in Gloucester County. The Corporation owns and controls twenty-five square miles of ore lands. The ore is a magnetic hematite and already upwards of 50,000,000 tons have been proven. This is by no means the limit of the deposit, which is estimated to contain hundreds of millions of tons. Of this mine Mr. John E. Hardman, consulting mining engineer, Montreal, says: "It is the largest body of merchantable iron ore known to me to exist in the Dominion to-day."

A railway has been constructed for a distance of seventeen miles, connecting with the Intercolonial Railway, over which ore can be carried to Newcastle, N.B., where docks having a loading capacity of 3,000 tons per hour are being constructed. The distance from the mines to Newcastle is about 56 miles. From the mines

of the Drummond iron range to Parrsboro the railway distance is about 231 miles, but it would be possible to transport the ore by water during about nine months of the year to one of the ports on Northumberland Strait, from which the rail haul to Parrsboro would be short. The railway distance from the Drummond Iron Mines via Newcastle and Oxford Junction to Pictou, N.S., is about 281 miles. During the months that Northumberland Strait is open the water route would be shorter. It might be found advantageous to smelt Drummond iron ore in the vicinity of Pictou Harbour. From the centre of the coal field to Pictou Harbour the rail haul of coal would be between thirteen and fourteen miles. Works located in Pictou County would have the advantage of being somewhat nearer to Montreal than those in Cape Breton are. The railway distance from Pictou to Montreal is about 797 1-2 miles via Oxford Junction and about 829 1-2 miles via Truro, while Sydney is about 985 miles from Montreal via Oxford Junction and about 988 1-2 miles via Truro. During the season of St. Lawrence navigation the deep water route is considerably shorter than the rail route, and of course much cheaper, the distance from Sydney to Montreal being about 726 miles, while from Pictou to Montreal the distance is about the same.

Iron and steel works located in Nova Scotia have the disadvantage of being at a great distance from the central markets of Canada. On the other hand, Nova Scotia has a wonderfully good geographical situation as regards the markets of the world at large. It is nearer to Europe than any other part of the mainland of America and, strange to say, it is nearer to the leading countries of South America and South Africa than the Southern States are.

With reference to the remarkable geographical position of Cape Breton, I may quote from one of a series of articles entitled "At the Front Door of Canada," which I wrote for the "Montreal Star" some years ago. The harbours of Sydney and Louisburg are the front doors of Canada. They might be called magic doors, for they open wonderfully into short passages to the leading markets of the world. It is an extraordinary fact that Sydney and Louisburg, while more than 2,200 miles nearer to Liverpool than New Orleans and Mobile, are at the same time nearly 600 miles nearer to Pernambuco, Rio Janeiro and Beunos Ayres, and nearly 900 miles nearer to Cape Town, South Africa. This is because ham-shaped South America lies far to the east of North America, while New Orleans, Mobile and other ports on the Gulf of Mexico, are a long distance west of the Atlantic Ocean. Moreover, ships from southern ports of the United States cannot take a direct route, because they have to steer clear of the West India Islands. Cape Breton, jutting far eastward into the Atlantic, is much nearer to a direct line drawn north from the east coast of South America. And the Gulf ports are not the only ones over which the Cape Breton ports have an advantage. The whole Atlantic coast of the United States slopes away to the southwest, and Savannah, Charleston, Baltimore, Philadelphia and New York are so far to the west of the direct routes from Sydney and Louisburg that the Cape Breton ports, although farther north, are much nearer to the chief ports of South America and Africa.

The most eastern point of South America is Pernambuco. All vessels going south of that point to Rio Janeiro, Beunos Ayres or other South American ports must pass it. The following table of distances in nautical miles will show the wonderful advantage that Sydney has over all American ports for trading with Great Britain and other countries of Europe, South America, Africa and Asia.

To Liverpool.

Sydney Harbour to Liverpool.	Miles.
(via N. Ireland)	2,282
(via S. Ireland)	2,307
New Orleans to Liverpool	4,553
Mobile to Liverpool	4,506
Savannah to Liverpool	3,571
Charleston to Liverpool	3,500
Newport News to Liverpool	3,157
Baltimore to Liverpool	3,324
Philadelphia to Liverpool	3,160
New York to Liverpool	3,110

To Pernambuco.

Sydney Harbour to Pernambuco	3,567
New Orleans to Pernambuco	4,146
Mobile to Pernambuco	4,133
Savannah to Pernambuco	3,660
Charleston to Pernambuco	3,631
Newport News to Pernambuco	3,591
Baltimore to Pernambuco	3,758
Philadelphia to Pernambuco	3,746
New York to Pernambuco	3,696

To Cape Town.

Sydney Harbour to Cape Town	6,467
New Orleans to Cape Town	7,355
Mobile, Ala, to Cape Town	7,309
Savannah to Cape Town	6,867
Charleston to Cape Town	6,831
Newport News to Cape Town	6,736
Baltimore to Cape Town	6,903
Philadelphia to Cape Town	6,870
New York to Cape Town	6,787

The distances from Sydney to the various points were furnished to the writer by the late Captain W. H. Smith, R. N. R., Chairman Board of Examiners of Masters and Mates, Marine Department, Halifax, while the distances from various American ports were compiled by the United States Commissioner of Navigation. Louisburg is not given in the above tables, but the distances from Sydney and Louisburg are practically the same. Only points on the east coast of South America and the west coast of Africa are given for comparison, but it will be evident to all who examine the map that Sydney must have the same advantage of distance in trading with the west coast of South America and east coast of Africa. It applies also to the whole Pacific coast of North America, to Asia and Australia. It seems strange, but it is a fact that Sydney is nearer to San Francisco than any Atlantic or Gulf port of the United States. The distances given are for routes for full powered steamships.

There are a number of harbours in Nova Scotia open all the year which, although not quite so near to the outside markets as Sydney and Louisburg, are better located in this regard than any port in the United States.

It should be noted, however, that unless regular steamship lines are established to the leading ports of the world the natural advantage of geographical situation will count for little except in the case of a large order for which it might pay to charter a ship to make a special voyage.

St. John, N.B., would possess some advantages as a location for a large iron and steel plant. The harbour is open throughout the year. It is one of the terminals of the Intercolonial Railway; it is the winter port of the Canadian Pacific Railway, and it is probable that both

he Grand Trunk Pacific Railway and the Canadian Northern Railway will have terminals there. It is nearer by rail to Montreal than any other important port in the Maritime Provinces. The railways taking grain and other farm products from central and Western Canada to St. John for export will be anxious to have return freights and would no doubt concede very low rates on finished products to an iron and steel company at St. John. St. John is the commercial metropolis of New Brunswick and is also well located for the distribution of its products throughout the greater part of Nova Scotia. With reference to the markets of the world, it is nearly 400 miles nearer to Liverpool than New York, and it is remarkably well situated for trade with Mexico, South America and South Africa. While not quite so near to world markets as Sydney, C.B., is, it has the advantage of having more established steamship lines There is little doubt that it will in the near future have first class winter steamship services to Mexico, the West Indies, South America, and South Africa, as well as to England. It is not probable that the summer service will ever be equally good on account of Montreal competition.

It is almost certain that a large steel shipbuilding plant will be established in St. John in the near future and some of the ships of the Canadian Navy may be built there. In the days of wooden sailing vessels it was one of the greatest shipbuilding centres in the world, and in ownership of ships ranked fourth among the cities of the British Empire.

Limestone could be obtained near St. John; coal or coke could be brought by water from the Cumberland, Pictou and Cape Breton coal fields; iron ore might be obtained from Torbrook, Londonderry, Arisaig and perhaps Newfoundland, as well as from the Drummond range near Bathurst in New Brunswick, and possibly some nearer point in New Brunswick. As already stated, Parrsboro, the port from which Springhill coal is shipped, is 82 miles from St. John, while the rail haul from the coal mines is 27 miles, and if Pictou coal were brought to St. John via Parrsboro the rail haul would be 132 miles, but this might be shortened by connecting Parrsboro and Truro. The water route from Pictou harbour to St. John is about 485 miles. The water route from Sydney, C.B., to St. John is about five hundred miles. The coal mines on the west coast of Cape Breton are somewhat nearer to St. John. Port Wade, N.S., from which the Torbrook ore is shipped, is about 40 miles from St. John. From the Drummond iron mines, near Bathurst, in Gloucester County, N.B., the rail haul to St. John via Moncton would be about 224 miles. The ore could be transported by rail to Fredericton, a distance of about 170 miles from the mines, and there transferred to boats running down the St. John River.

It has been suggested that blast furnaces might be constructed in the vicinity of the Bathurst mines or at Newcastle, getting coal from Cape Breton, Pictou County, or the Cumberland field. This would be a case of carrying coals to Newcastle in a new sense.

When other advantages are equal, it is more economical to carry iron ore to coal than coal to iron ore, for the coal is much more bulky and more difficult to handle. By converting the coal into coke the bulk is greatly reduced, but the coke requires much more careful handling in transportation than coal.

(To be continued.)

SUMMER ROUTE TO THE PORCUPINE.

(Written for the CANADIAN MINING JOURNAL by Hamlin Brooks Hatch.*)

At the present time, the question of the most feasible route into the new Porcupine gold fields is one of moment to mining men and investors who have interests in the new field. In other years in which any new mining country has been opened up in the winter months, men have been able to figure with some degree of certainty as to the time of the winter break-up. The spring of 1910 has been remarkable in Ontario, owing to the fact that the streams and lakes opened at least four weeks in advance of the time expected. Interested people who placed their faith in records of the break-ups of other years, and who therefore failed to get their supplies in over the good winter roads, are at present forced to devise a good freight route for the conveyance of all mining necessities. So the question of a good summer route into this new country is one of greater importance than it would at first appear.

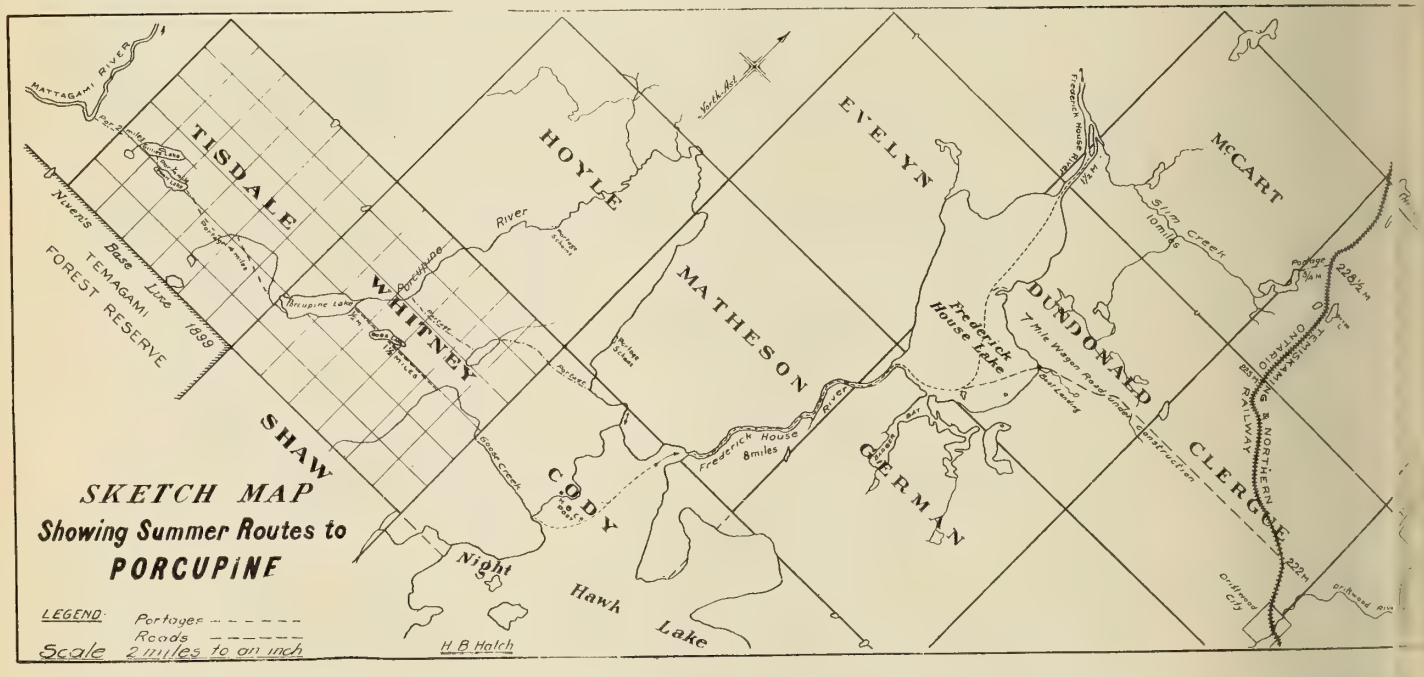
There are at present four possible routes, two of which are being used now. It is the purpose of the writer to take up each separate route in turn, giving its advantages and disadvantages from both the passenger and the freight standpoint. The writer is himself familiar with two of the routes that will be discussed. The other two have been taken from the Government map of the district and are at present simply possibilities for the future.

Route from 228½ Mile Post.

The first route to be considered will be that starting from the 228½ mile post of the T. & N. O. Railway. This can be termed the all-water route. The station name is Holland. There is one train a day arriving between 7 and 9 p.m., going north, and at 9 a.m., going south. There is a good clean stopping place at this point.

From the steel there is a three-quarter mile portage to Small Lake, at the head of Slim Creek. This portage is good travelling, it being part of an old lumber road. Just before reaching the lake there is a steep down grade. Coming out, the lumber road may be taken, which winds up over the grade, lessening the incline considerably. From this lake it is a short paddle to the mouth of Slime Creek. This creek, which is 10 miles long, is narrow and quite fast. The first six miles from the lake the stream is more or less choked with dead trees and debris, which necessitates the careful handling of the canoe. The last four miles is open and good. The time of going in through Slim Creek to the Frederickhouse River is two hours. Coming out it takes four hours. Slim Creek empties into the Frederickhouse River 1 1-2 miles below the Frederickhouse Lake. Here the current is very fast, and it is necessary to pull the canoe from the shore. It is possible to paddle some of the distance, but the last quarter of a mile runs like a mill-race and no one has as yet been able to negotiate it without resorting to tracking. The west shore is sandy and furnishes a good foothold for this work.

From Frederickhouse Lake it is possible to use



launches all the way into Porcupine Lake. The launches which are to be used are the regular flat-bottomed pointers fitted with engines.

From the head of Frederickhouse Lake the route continues over the five miles separating Nighthawk Lake from Frederickhouse. From the head of Nighthawk it is a short distance to the Porcupine River. This river empties into Porcupine Lake. It is a good wide stream, and throughout its whole length there are only two portages, and both are short, being only five chains. The route ends at Porcupine Lake.

The advantages and disadvantages of this route are about equal. The greatest point in its favour is that with the establishment of launches and the building of good tote roads over the two short portages on the Porcupine, heavy loads of freight can be taken in with scarcely any re-handling. From a passenger standpoint, the route is not advantageous. Time consumed making the trip is the most important objection. Go-

Lake. The route will continue into Goose Creek, whi empties into Nighthawk, just south of the Hudson B Post. Leaving Goose Creek, there is a 1 1-2 mile por age into Bob's Lake. From Bob's Lake there is a on half mile portage into Porcupine. It is intended build good summer roads over these last two portage There should be no difficulty in making the distan either way in one day.

To the writer's mind, with the completion of the sur mer roads, this route furnishes the logical way into t gold fields. Especially is this so from the passenger standpoint. Travellers can easily save 24 hours on t trip by this route. The writer understands that t building of these tote roads at present is being done mining men interested in the country. It would see that the Government should at least do its share opening up this new gold field by financial help in t building. It is impossible to say at the present tir whether or no this route will be best for freight

ing in the sixty-mile canoe journey takes 2 1-2 days, and coming out 14 hours. Of course, with the running of the launches the time will be considerably reduced. It may be said that the writer believes Slim Creek would be at slight expense made safe for the running of light draught launches and that this would make the route practically an all-launch one. The one great objection to this route is that a thirty-mile distance as the crow flies is more than doubled.

The Route from 222 Mile Post.

It will be remembered that mile post 222 was the jumping-off place from which the old winter road started for the Porcupine. Parts of this old winter road are at present being changed so as to be passable during the coming summer. The streams and lakes along the route are used wherever possible.

The route starts from 222, from which a seven mile wagon road will lead due west to Frederickhouse Lake. This wagon road at present is completed for three miles. The four miles remaining will be ready for use shortly. As proposed now, probably only a half mile of this distance will have to be corduroyed. At the Frederickhouse, launches will meet the wagons, and from there the 228 1-2 mile route will be followed with Nighthawk

otherwise. Whether it will be cheaper to re-handle t stuff a number of times than to carry it over the a water route over twice the distance, with practica no re-handling, will have to be determined by expe ment.

The present prices of freight from 222 to the Fred ickhouse are $4 for 100 pounds. This is exorbitant, h is partly justified at the present time by the state the roads. There is no regular passenger service is ye yet on this route. It may be said, however, that t route seems to solve the transportation question as w as it can be solved under the circumstances.

One point which, in regard to both of the abo routes renders them disadvantageous, is the low wa at present prevailing in Frederickhouse Lake a River. This low water is directly due to the blow out of High Falls by Father Paradis. At present at southern end of Frederickhouse Lake there is fr three-eighths to one-half mile of sandbar covered only six inches to a foot and a half of water. It s necessary to pack goods over this distance, as it is impossible to paddle it without running aground. Th are, to the writer's mind, two ways to remedy t Either dam up High Falls or blast out a channel in

lake. It is the opinion of interested people that the Ontario Government should take this matter up at once and provide the necessary money to do either of these things. Time is a matter of importance and there should be no delay. The rendering of Frederickhouse Lake of sufficient depth for launches will solve as well as possible the difficulties of transportation which at present cause trouble.

Other Possible Routes.

There are two other possible routes into the Porcupine country. The writer is not familiar with them, and the data concerning them were obtained from the Government map. Both of these routes have as their main road the Mattagami River.

The more logical of the two starts from Bisco on the Canadian Pacific Railway, from where a trip of 140 miles is taken to Niven's base line. There are numerous portages along this route. A portage of three miles along Niven's base line into Gillies Lake marks the end of the route. Gillies Lake is in the western part of Tisdale Township. The other route necessitates the taking of a construction train west from Cochrane station on the Transcontinental, to the Mattagami River; from there, canoes or launches, 60 miles up the Mattagami to Tisdale Township. There are a number of portages and the going is all against the current. The chief disadvantage of both these routes is their length.

In conclusion, the writer wishes to say that there is no question that with the completion of wagon roads over the different portages, and the installation of launches on the lakes and streams, together with a lowering of the rates now being asked for transportation ,both on freight and passengers, to a fair price, the route as proposed from 222 mile post will solve this question of access to the Porcupine gold district as well as it can be solved under the prevailing conditions.

---

*Mining Geologist, Cobalt, Ont.

AUSTRIAN NOBEL DYNAMITE.

The accounts of the Nobel Dynamite Company, of Vienna, for 1909, show net profits from the four factories of 1,566,000 crowns, as compared with 1,734,000 crowns in the preceding year, and it is proposed to pay a dividend of 25 per cent., being the same rate as in 1908. According to the directors' report the decrease in the financial results was due to the smaller consumption of dynamite owing to the completion of the great mountain railways and the decline in the general situation of trade, whilst the orders for war ammunition were not up to expectations. With regard to the prospects for the current year, the report states that the quite extraordinary increase in the price of glycerine has to be taken into consideration, and existing competition will not permit of a corresponding advance in sale prices. A works was established in Hungary in the past year for the manufacture of nitrate of ammonia explosives, and in view of this fact the Nobel Company proposes to undertake shortly the production of similar and also first-class explosives which have answered the purpose in every way abroad.

The total value of New Brunswick's mineral production for 1908 as computed by Mr. John McLeish, of the Mines Branch, Ottawa, was $579,816. This was only 0.68 per cent. of the total value of the Dominion production.

WESTERN BRANCH MINING INSTITUTE.

The eighth general meeting of members of the western branch of the Canadian Mining Institute will be opened at Grand Forks, on Thursday afternoon, May 26, when routine business will be transacted and several papers having particular reference to the Boundary read and discussed. The director of the Geological Survey of Canada (R. W. Brock) has courteously given permission to Messrs. C. E. Le Roy and L. Reinecke, staff geologists, to take part in the proceedings, and the former will contribute some notes on the geology of Phoenix camp, while the latter will take the West Fork of Kettle River as his subject. Other papers expected are, respectively, on the early history of mining in the Boundary, the electric power transmission system of the district, and probably some notes concerning local transportation facilities. The chairman of the branch, W. Fleet Robertson, Provincial Mineralogist, will endeavour to attend the meeting, arrangements for holding which are being made by the branch secretary, E. Jacobs, of Victoria. Incidentally, it may here be mentioned that as a result of action taken by the branch upon a resolution submitted at the meeting held in Vancouver on February 25, by A. G. Langely, having for its object the provision of facilities for telegraphic communication with Stewart, at the head of Portland Canal, the sum of $16,000 for this purpose has been included in the Dominion supplementary estimates and it is stated that an effort will be made to establish telegraphic communication with Stewart during the current year.

In a recently published tabular statement, compiled by Mr. C. O. Schmitt, a member of the Institution of Mining and Metallurgy, some instructive figures are given as to the relative weights and sizes of stamp-mill parts. Five separate stamp-mills, all on the Rand, are used for illustration. The weights of stamps range from 1,250 pounds to 2,000 pounds. In the former stamp the different parts bear a relation to each other quite different from that obtaining in the heavier stamp. For instance, in the 1,250-pound stamps used on the Simmer & Jack mines, the stem weighs 580 pounds, and constitutes 46.4 per cent. of the total weight; whilst in the 2,000-pound stamps used in the City Deep, the stem weighs only 556 pounds, and constitutes but 27.8 per cent. of the total. In the former stamp the dimensions of the stem are 3 1-2 inches by 18 feet; in the heavier stamp the dimensions are 4 inches by 13 feet. "The head," says Mr. Schmidt, "is a vital part of the stamp and its importance has been more fully realized since the introduction of the heavy stamp. It is evidently that part of the stamp which must mainly serve to increase the weight of the latter, for the reason that its weight does not decrease as does that of the shoe, and also because its weight acts immediately upon the rocks to be crushed. With an increased size of stem the head also had to be increased so as to give the required strength, but as there is a limit in this direction imposed by the distance from centre to centre of stamps, the additional weight required is generally obtained by increasing the length until, at the present time, the length has in some cases reached 4 feet.

The production of nickel from the ores of the Sudbury district in Ontario was more than doubled between 1904 and 1906.

MINING ENGINEERING IN CONNECTION WITH FORT WILLIAM'S WATER SUPPLY.

(Notes from paper read before the Canadian Society of Civil Engineers, by H. Sydney Hancock, Jr.)

[Editor's Note.—The following extract from Mr. Hancock's paper throws a valuable sidelight on a phase of civil engineering that overlaps the realm of mining. Our readers will note the arrangement of drill holes on the headings. From the progress made and the large consumption of explosives, it seems probable that an experienced mining engineer could have effected a considerable saving, particularly in the item of time. We request our technical readers to comment upon the practice here outlined. But whatever fair criticism may be made of Mr. Hancock's mining, it is but just to commend highly the care and thought that marked all his work.]

Power.—Steam was practically out of the question for this purpose. Coal must first come from Pennsylvania, and then be hauled seven miles over a road that took many months to get into passable condition, and had some hills with 15 and 20 per cent. grades. The local supply of wood was limited, and although used only for heating purposes, had to be hauled more than three miles before the close of the work. Gasoline figured out at over $100.00 per h.p. Electric power at $25.00 per h.p. was available on the north side of the river, and it was decided to build a power line, although, unfortunately, the price of copper was at the time abnormally high. The current used was supplied by the Kaministiquia Power Company from their hydraulic plant at Kakabeka Falls—at 2,200 volts, three phase, 60 cycles alternatiing current. Poles, 35 feet in length, were secured from the surrounding country, and spaced 150 feet apart. Two four-pin cross arms were used on each pole, the lower arm carrying telephone lines. The wire was No. 6 solid weather-proof copper, running 112 pounds per thousand feet. The river was crossed by a lead-covered submarine cable of No. 6 copper, laid just within the trench dredged for the west pipe crossing. This cable remained undisturbed for nearly two years, after which it was a constant source of trouble. The first break, early in November, 1908, was caused by a dragging ship's anchor, and nearly five weeks elapsed before a new cable could be secured. The cable was so buried that only 100 feet could be salvaged, after three days' work with scow and diver. The following temporary expedient was adopted to replace it. Three lines of ordinary W. P. stranded copper wire, heavily taped, were bound together. The cable thus formed, was passed through eight lengths of 2 1-2 inch fire hose, and lowered to the bottom with fish plates, lead pipe, and other weighty debris. This worked well for two weeks, when another boat hooked the hose and punctured the rubber. It was taken up and dried, and again laid for a further run of five days. This performance continued until the arrival of the new cable, shortly before the close of navigation. On opening of navigation during the present year (1909), the water level of Lake Superior and the Kaministiquia River was about two feet below normal, and the first boat down the river scraped the cable so that it had to be raised and dried. About two weeks later one wire went dead, and it was thought inadvisable to attempt to dry it again; consequently, one of the taped wires previously used in the fire house was strung through a one-inch lead pipe and connected at the shore ends. No further trouble has been experienced.

The cost per mile of the transmission line, excluding telephone, was as follows:

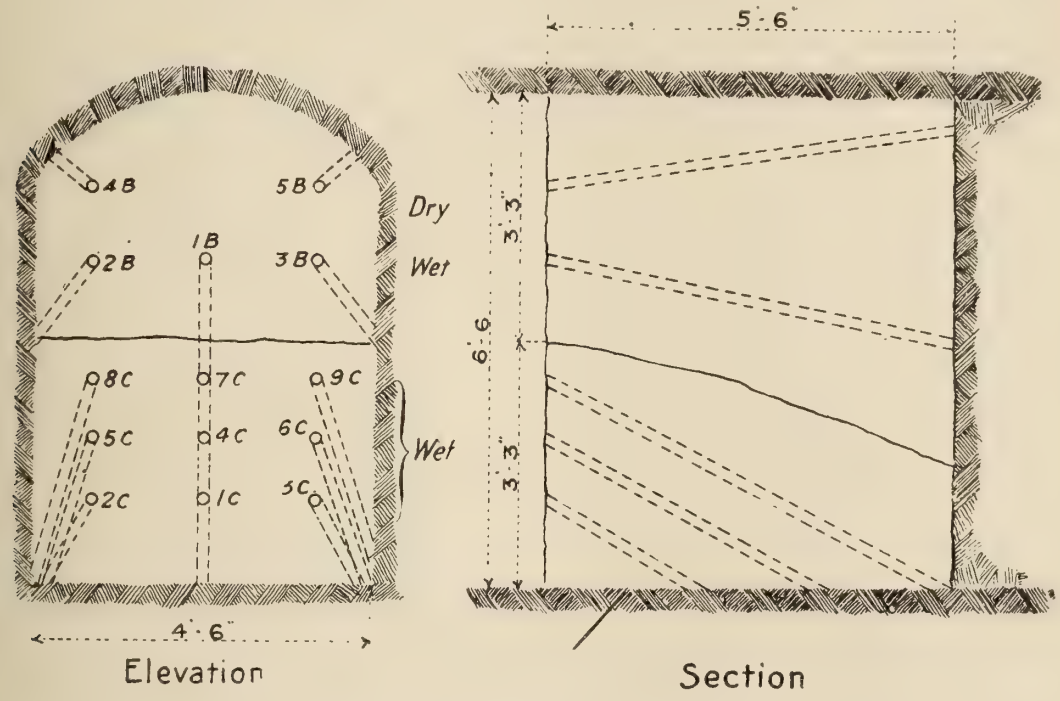
3 miles, 1770 lbs. No. 6 Wire, at 28c..	$495.60
35 Poles in place, at $5.00.....	175.00
35 4-pin Cross Arms, at 41c.....	14.35
105 Birch Pins, at 2 1-2 cents	2.62
35 Cross Braces, at 8c.....	2,80
105 Double Petticoat Insulators, at 4c	4.10
Freight, at $1.20 per 100 lbs.....	24.00
Labour Stringing Wire	30.00
Total per mile	$748.47

The total expenditure on the line was as follows:

7 miles completed Line, at $748.47..	$5,239.29
Cable and Work at River	358.20
Alterations and Repairs	317.00
Repairs and Renewals on Cable	580.00
	$6,394.49

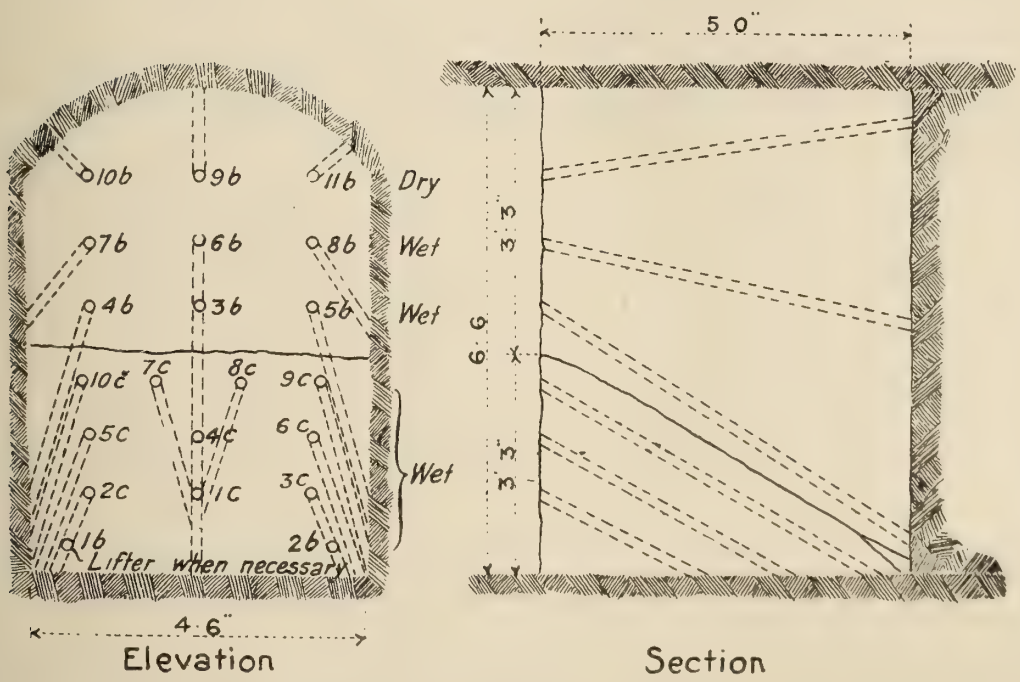
The alterations were due to the necessity of three times changing the four-pole construction crossing the C. P. R. property to accommodate increased trackage, and of moving the line from the vicinity of a particularly heavy rock cut in the second pressure main.

Plant.—A class E straight-line belt-driven Rand air compressor, capable of compressing 282 cubic feet of free air per minute to a pressure of 100 pounds per square inch, was erected at the main camp. This compressor was operated by a 50 horse-power Westinghouse induction motor, through three 15 kw. 2,200 volts to 550 volts, transformers. A 4-inch air pipe, fed by a 36 inch by 8 feet receiver erected in the compressor house. From this air receiver 3-inch wrought iron pipes, with a union joint every 200 feet, led to the shaft and north portal. At these points were placed 24 inch by 6 feet air receivers, from which 2-inch pipes served the various headings. The 3-inch pipe was carried on the surface of the ground, blocked up where necessary to secure a continuously falling grade. Serious trouble from frost not being anticipated, the expense of excavation in a rocky country was avoided. During continuously cold weather, with temperatures near the zero mark, no trouble occurred, but, at almost every mild spell, work was temporarily stopped by frozen air pipes, a cold night, after a comparatively warm day being the chief cause. It was not feasible to cover the whole line with snow, owing to its height above the ground when crossing small ravines. To overcome this difficulty, drip cocks, threaded to take a small pressure gauge, were placed every 300 feet along the line, and a supply of wood and coal oil kept at numerous points. When a block occurred, a gauge inspection revealed the 300-feet strip affected, and an hour's work or less usually sufficed to thaw it out.



The drills used were No. 43 Rand "Little Giant" drills, with 3-inch cylinders, mounted on 6-feet double screw mining columns, and fed through 50 feet of 1-inch Monarch hose.

Black Diamond steel, with regular cruciform bit



was employed at the commencement of the work in the comparatively soft rock, but the change to the hard black basalt necessitated the use of the best grade drill steel, manufactured by the Jessop and Edgar Allen Companies.

The track was of 50 c.m. gauge, 12-pound rails, 15 feet long, laid on 4-inch by 6-inch by 30-inch ties, spaced 30 inches C.—C. The curves and switches were made of Koeppel portable track on steel ties.

The four cars at the north portal heading were Koeppel all-round dump cars of 18 cubic feet capacity, and at the shaft headings eight detachable body-side dump roller-bearing Koeppel cars of similar capacity were used.

Average Ground

Hard Ground.

SKETCH SHOWING ARRANGEMENT OF DRILL HOLES.

A 5-inch double cylinder Jenckes hoist, operated by compressed air, with a 6-inch by 24-inch drum winding a half-inch steel wire rope, was erected at the shaft.

The shaft sump was drained by a Cameron pump, with a 3-inch suction and 2-inch discharge, rated at 100 imperial gallons per minute and operated by compressed air.

Buffalo forges were used at each end, but the centrifugal blowers were replaced by a compressed air nozzle.

Ventilation was secured by two belt-driven blowers, with 12-inch blades operated by 2 horse-power Westinghouse motors, fed from the lighting circuit and delivering air through a 5-inch pipe made up into 20-foot lengths of 24-gauge galvanized iron.

The dry, hard nature of the rock in the north shaft heading caused much inconvenience from dust, and necessitated the use of a spray, which was furnished from the shaft pump through a 3-4 inch wrought iron pipe.

Light was provided by a single-phase 110-volt circuit, through No. 12 weather-proof wire, from which 16 candle-power lights, protected by wire guards, were dropped every 75 feet. The "breast" work was lighted by a heavily guarded 32 candle-power lamp, furnished with socket handle and hook, and attached to 100 feet of rubber-covered extension wire.

TUNNEL.—The smallest cross-section, consistent with reasonable progress during construction, being more than sufficient for the contemplated water supply, the minimum finished dimensions were specified to be 4 feet by 5 feet 10 inches, carried at a grade of 1 in 1,000.

It was the original intention to line the whole tunnel with concrete, varying in thickness with the nature of the material excavated, but, finally, only those portions showing any sign of weakness were so treated. The generally close, hard nature of the rock removed all fear of seepage or erosion, and the use of a very high co-efficient of roughness still brought the delivering capacity of the tunnel considerably over any possible discharge that could be secured from the watershed.

The rock was excavated on a minimum cross-section, 6 feet 6 inches high by 5 feet wide, and all weak sections lined with 1:2½:5 concrete, leaving a clear waterway, 4 feet wide and 5 feet high, to the springing line of a segmental arch of 4 feet span and 10 inch rise.

Work was carried on at three headings with three machines, two working north and south from the shaft and one working south from the north portal.

SHAFT.—The shaft was sunk at Station 9 + 68, 60 feet in depth and 12 feet by 8 feet inside dimensions. Four sets of 12 inch by 12 inch timber, 6 feet C.—C., backed by 3-inch sheeting, brought the excavation to solid rock. The shaft was divided into two compartments by 2-inch plank casing, the hoisting compartment being 8 feet by 8 feet, and the ladder, pipe, and wire compartment 3 feet 9 inches by 8 feet. Three "rollers" or landing platforms were provided in the latter, making three 16-foot stages and one of 12 feet.

The shaft was sunk by hand labour, prior to the arrival of the machines, at an average rate of 1 foot per shift. An ordinary "jack roll" was used as a hoist.

The head gear was carried on four 12 inch by 12 inch posts, braced against the hoist by 12 inch by 12 inch struts. A 24-inch sheave was supported on two 8 inch by 8 inch timbers, bolted to four 4 inch by 12 inch cross-timbers, which were again supported by four 4 inch by 12 inch timbers, secured to the posts by 3-4 inch bolts, and a shaft house of 1-inch lumber covered the erection at the collar of the shaft. 12 inch by 12 inch stringers, to each of which was spiked a 40-pound rail, formed a track of 6 feet 9 inches gauge, on which ran a platform car fitted with a section of track 19 5-8 inch gauge of 12-pound rail.

The cars used in the shaft drifts were the Koeppel steel side roller-bearing dump cars with detachable bodies. To the hook of the gin block was attached the Koeppel crane attachment. When the cars were brought to the shaft, the bodies were hoisted clear of the trucks to the pit head. A duplicate truck was then run in on the platform car over the shaft, the body car lowered into position, and the platform car run clear to a point where the dump track joined the platform track. The full dump car was then pushed on to the dump track and replaced by an empty car standing on the adjoining "empties" switch, the platform run over the shaft, and the empty car body attached to the crane. On the removal of the platform, the car body was lowered to the vacant truck awaiting it. The full car was then dumped by the "lander" and returned to the "empties" switch. Under ordinary circumstances, this method would have proved cumbersome, but the uniform hardness of the rock in both shaft headings reduced the quantity of material to be handled to the capacity of one "mucker," and as the "landers" soon became "speedy" at their work, this method of hoisting rendered satisfactory service.

The alignment was transferred down the shaft on an 11-foot base line by 12-pound plumb bobs attached to fine piano wire and resting in buckets of water. A transit was then set up in line with the wires and the line produced. This operation was repeated several times whilst the drifts each made 200 feet of progress, and, finally, a centre line 300 feet in length was established on the mean of the five middle readings.

When the south heading was driven through, the alignment was checked by setting up on a hub near the shaft the back sighting 700 feet to a hub set from the surface at the south portal. The error at the breast of the drift heading north was found to be 1 1-4 inches, and was corrected by subsequent operations.

At the north portal Koeppel steel all-round dump cars of 18 cubic feet capacity were also used, the steep hillside affording ample dumping ground for the whole work within a haul of 200 feet from the portal.

The cars were all pushed by one man, and over distances of approximately 1,000 feet. Bye-passes were excavated and a switch installed so as to reduce the haul of the mucker at the breast to that limit. A small Koeppel flat car was provided for handling machines and tools for each drift.

Owing to the scarcity of capable machine men, the work was at first carried on by 10-hour "shifts," but as men became available, three 8-hour "shifts" were organized. A "shift" consisted of one machine man and his helper, and from one to three muckers, depending on the length of haul and character of the work. Two blacksmiths, one at either end, each worked from 10 to 14 hours, varying with the hardness of the rock and the quantity of outside work. The hoistmen and landers at the shaft, as well as the compressor men, worked in two "shifts" of 12 hours. The track-laying, pipe-laying, light extensions, machine and general repair work was handled by two men working usually 10 hours.

The first 1,200 feet of the north heading consisted of a compact blue volcanic ash slate that drilled and broke well, and through which good progress was made. The remainder of the tunnel was through a tough, hard trap, containing numerous diorite dykes of phenomenal

hardness, the specific gravity of which frequently reached 3.4.

Progress through the latter rock was painfully slow, although air was delivered to the machines at from 80 to 85 pounds pressure. Bits of the best steel, tempered to a pitch that would notch a file, were worn smooth and useless without a crack or flaw after drilling less than three inches. It frequently took over three hours to drill a 5 feet 6 inches dry back hole.

The machines were mounted on standard vertical mining columns with two jack screws, the small size of the drift preventing the use of a horizontal bar.

The average advance made by each cut was four feet six inches. In the slate rock eight five foot holes sufficed, the whole breast being fired in one blast, but the tenacious nature of the hard rock sections necessitated from seventeen to twenty-two holes, in order to break the full cross-section. The holes were arranged as shown in the sketch, and the lower nine holes forming the "cut" were fired first with a fuse, timed to explode in the order shown. After the "muck" had been cleared, the "back" holes were similarly fired.

The upper five holes in the back were practically "dry" holes, and proved a very hard drilling proposition in this rock. Two lifters were sometimes used at the bottom of the face to serve the double purpose of striking to the bottom of the cut, and lifting the "muck" away from the face. thus facilitating the speedy erection of the columns for the next attack.

Work commenced with sixty per cent. dynamite, manufactured by the Ontario Powder Company, but the fumes proved too much for the miners, who were constantly being overcome by gas, and forty per cent. dynamite was substituted with satisfactory results. When the very hard rock was encountered, the writer believed that a stronger explosive would be advantageous, and Nobel's seventy-five fumeless gelignite was adopted. After some trouble in getting it properly thawed, and the holes intelligently loaded, the results secured were good, but its odour, to which the "copper country" miners, who were in the majority, were unaccustomed, caused much vomiting and the experiment had to be abandoned. In the slate rock, about six pounds of 40 per cent. dynamite were used per foot of completed tunnel, but in the hard rock it was necessary to use from twelve to eighteen for the same distance.

In the slate rock firing by battery was more or less successful, but in the hard rock, time fuse gave infinitely better results. The "Bennett' fuse was used throughout the work and proved of uniform excellence.

Two accidents marred the success of the work. One on June 21st, 1907, and the second on June 21st, 1908. On the first date the two shaft drifts had each been driven less than forty feet, the ventilating fans not being then in position. Immediately after the midnight blast the two miners in charge of the shifts went down to recharge a missed hole, expecting to get away before becoming affected by the fumes. The air hoses were coiled on the lower "soller," and the precaution of blowing out with compressed air was not taken. Apparently both men were overcome immediately on reaching the bottom ladder, as one sustained a broken arm from the fall. A rescue party of two men from the surface placed the unconscious miners in the bucket, and then attempted to climb out, but both collapsed on the lower "soller." The casing had not been completed in the ladder compartment, so they were hoisted to surface by the bucket. One man, and he the most active of the rescue party, was already dead from the effect of the fumes and the effort of carrying a collapsed comrade up the first ladder. His name was Jos. Chichester, the son of Colonel Chichester, a distinguished British veteran of the Indian Mutiny.

Within a few minutes of one year later, a mucker in the north heading, whilst cleaning up in preparation for the blast, turned up a small piece of dynamite eight feet from the face. On being advised, the man left his machine and began to search with a pick for further fragments, thereby immediately causing an explosion. Both the machine man and his helper were killed and one mucker was permanently blinded, the other standing beside his car, six feet away, was uninjured. The amount of dirt moved did not exceed a cubic foot, but the whole quantity was apparently received in the faces and chests of the victims. Neither the air hose nor the light wire was damaged, and the incandescent globe hanging from the column, only five feet away, was uninjured. Subsequent examination pointed to the probability that the explosion of No. 3 cut hole had cut off No. 6, drilled in this case a few inches below grade, and leaving an inch or two of dynamite in the bottom of the latter hole. An extraordinary feature of the case was that this was the third time the hole had been mucked over, and as half of it showed plainly on the side of the drift it had been examined two days previous to the accident.

The machines commenced work on the 4th day of June, 1907, and the two long headings met at Station 27+56 on the 24th day of May, 1909. The closing error in alignment amounted to three-eighths of an inch, and the difference in elevation was 0.05 feet.

After the tunnel had been cleared out and concreted where necessary, the shaft was covered eight feet above grade line by a 24-inch slab reinforced by old twelve-pound steel rails, supported on walls four feet apart keyed into rock at the sides with 1 1-8 inch drill steel. At the sump, the wall was made three feet wide on top, battering on the outside at 1 in 6. The whole shaft was then filled to the surface with earth.

The monthly progress in the three drifts was as follows:

	N. Portal. Drift.	N. Shaft. Drift.	S. Shaft. Drift.	Total feet.
1907.	ft.	ft.	ft.	ft.

Totals	2255	1798	766	4819

The wages paid on the tunnel were as follows:

Tunnel Superintendent	$150 per month.
Machine men	$3.50 to $4.00 per shift.
Helpers	3.00 to 3.50 per shift.
Muckers	2.50 to 2.75 per shift.
Landers	2.50 per shift.
Hoistmen	.25 per hour.
Blacksmiths	.35 to .40 per hour.
Blacksmiths' helpers	.25 per hour.
Compressor men	.25 per hour.
First mechanic	.40 per hour.
Mechanic's helper	.30 per hour.

OXYGEN BREATHING APPARATUS IN PACIFIC COAST COAL MINES.

By E. Jacobs.

One of the results of the efforts of the United States Geological Survey to make its important exhibit at the Alaska-Yukon-Pacific Exposition, held last year at Seattle, Washington, U.S.A., of practical usefulness to the mining industry is now manifest in the increasing interest being taken in the matter of providing the coal mines of the West with oxygen breathing apparatus for use in cases of need, primarily for life-saving purposes, and next for use in cases of underground fires or other emergencies. The United States Survey exhibit at that Exposition was a comprehensive one, and it included two Draeger helmets with the usual accessories to make this rescue apparatus complete, and in order the better to impress coal miners and others with the serviceableness of the apparatus, which few visitors to the Exposition had ever seen before, a demonstration was made every week day afternoon in a specially constructed room filled with noxious fumes. In this room, which was fitted with large glass windows, the two demonstrators could be seen at work climbing over obstacles, lifting heavy timbers, carrying dummy bodies, etc. In addition to the object lesson thus given, the official in charge of the demonstration work showed the apparatus to all wishing to closely examine it, explained its uses, fitted it on those who desired him to do this, and in every way possible endeavoured to impress enquirers and onlookers with the great value of the apparatus for the purposes designed. Shortly before the close of the Exposition an urgent call came from Roslyn, Washington, for the loan of the apparatus for use in a real emergency, a disaster having occurred in a coal mine there, unfortunately with distressingly fatal results.

The need for the provision of similar apparatus and training in its use having been thus demonstrated, some of the mines in the State were shortly afterwards equipped with the Draeger apparatus, and within four months of the closing of the Exposition a Mine Rescue Training Station was established at Seattle, with an official of the Technological Branch of the United States Geological Survey in charge. Dr. J. A. Holmes, of Washington, D.C., is head of this branch of the Survey, and he placed Mr. H. M. Wolflin in charge of the training station at Seattle. Quarters for the station were found in the building erected in connection with the A. Y. P. Exposition for the Philippine Islands exhibit, which building was one of those left on the campus of the University at Washington in accordance with the understanding reached (when the use of the campus for Exposition purposes was granted) concerning the leaving of certain buildings for university use after the close of the Exposition. The proximity of this building to the main university buildings was an advantage in another respect, namely, its nearness made it convenient for some of the university professors to give lectures in connection with the work of training in progress at the station.

In the mine rescue training work Mr. Wolflin has an assistant. The training course is taken chiefly in a suitable room or compartment strewn with obstacles such as would be met with in actual rescue work in a coal mine. The atmosphere of this room is made as foul with fumes as that of a mine in which rescue work would have to be undertaken. In addition to instruction in the use of the Draeger oxygen breathing apparatus and the actual wearing of the helmet in the room filled with noxious fumes, those taking the training course are required to attend from five to ten lectures delivered by members of the faculty of the University of Washington. In order to break what might otherwise be the monotony of taking the training course, suitable literature is provided in a reading room. Much interest has already been, and is being, evinced in the work of this training station by coal mine superintendents, foremen, fire bosses, and ordinary miners, and already advantage has been taken of the opportunity to become familiar with the mine rescue work, under conditions less dangerous than when there is no such provision made to save life, by a number of those directly concerned. It is gratifying to find that the training station at Seattle is making a record of men duly qualified and certificated during the first six months of its operation. It was opened on February 12 of the current year, and by the end of April certificates had been issued to thirteen men who, after taking the prescribed course of training, had proved themselves entitled to them. A station at Pittsburg, Pennsylvania, also operated under the auspices of the United States Geological Survey, after having been two years in active existence, has during that period issued only 25 certificates; one at Urubana, Illinois, during eighteen months has issued two, and one at Knoxville, Tennessee, four, after having been operated six months. It is evident, therefore, that advantage is being taken by western coal mining men of the opportunity afforded them by the opening of the station at Seattle in larger degree than by others elsewhere for whose benefit similar facilities for mine rescue training have been provided.

It is worthy of mention that the instructions given by the United States Geological Survey to Mr. Wolflin were so wide that when a recent emergency arose at Nanaimo, Vancouver Island, B.C ,he was at liberty to respond immediately to a request that he render assistance. Fire had broken out underground in one of the coal mines of the Western Fuel Company. Mr. Thomas R. Stockett, manager of this company, had already taken the lead in the province in procuring Draeger apparatus, which had been supplied more quickly than the selling agent had expected it would be, consequently the agent had not yet reached the mine in order to give the requisite instruction in the use of the helmets. However, Mr. Wolflin's services were immediately available, and he proceeded from Seattle to Nanaimo and there instructed a number of men how the apparatus could be used underground, so that the measures necessary for

extinguishing the fire could safely be undertaken. In this way a restoration of safe working conditions was expedited and the usefulness of the new addition to the equipment of the mine was demonstrated in a practical way.

Since the occurrence just mentioned Mr. Stockett has been invited by Mr. Wolfin, acting in his official capacity as mining engineer in charge of the station, to send some of his men to Seattle, there to take the mine rescue station training course, for which there would not be any charge made. The expenses of maintenance of this station are at present borne by the coal mine operators of the State of Washington, and Mr. Anderson, president of their association, has stated that operators of coal mines in British Columbia will be heartily welcome to send in some of their men to take the training course without charge. However, while it is probable some men from the province may avail themselves of this opportunity to obtain the requisite training, it is not likely British Columbia mine owners will take advantage of the generosity of their neighbours across the international boundary line to the extent of allowing their men to be trained without charge. The cost of giving a man the course of training, which lasts about two weeks, is approximately $30. The cash receipts on this account are all dealt with by Mr. D. C. Botting, Inspector of Coal Mines for the State of Washington, who attends to the proper disbursement of all money received. This arrangement frees the official representative of the United States Geological Survey from any connection with the financial affairs of the training station.

The great importance of this subject of mine rescue work is becoming generally recognized by coal mine operators. Now that the Western Fuel Company has shown itself alive to the necessity for adopting modern safety measures there is reason to conclude that other mining companies operating in Western Canada will speedily follow so good an example.

The Western Branch of the Canadian Mining Institute, at its meeting held in Vancouver, B.C., on February 25 last, passed a resolution requesting the Dominion Government to arrange for the admission duty free of oxygen breathing apparatus for mine rescue work. This request was forwarded to the Hon. Wm. Templeman, Dominion Minister of Mines, but it is not known whether or not the Government took any action thereon. It was stated at the Institute meeting that the United States Government had exempted such apparatus from duty on its being brought into that country, which was an important consideration in the equipment of mines with such apparatus. Another point urged in connection with the use of oxygen breathing apparatus was the great desirability of having it uniform in character, so that the equipment of one mine might be interchangeable with that of another. The distinct advantage of having the equipments of several mines, together with men trained in the use of it, rushed to the scene of any serious disaster was urged, and the hope expressed that mine owners generally will recognize the especial need for uniformity, so that in times of great emergency there may be readily available ample rescue equipment and many men trained in its use.

Quartz, occurring with feldspar, is shipped from the Richardson mine, Bedford Township, Ont., to the electric furnaces of the Electro Metals Company, Limited., Welland Ont. This company operates four furnaces, of from 1,000 to 1,500 h.p. each. Ferro-silicon is here manufactured.

THE CHIBOUGAMAU COMMISSION.

The Chibougamau region lies about 200 miles northeast of Lake St. John, and 5 miles to the south of Lake Mistassini. Excepting the early explorations made in 1674 by the Jesuit Father Albanel, the first report of importance was that by James Richardson, who examined the district geologically in 1870. Richardson mentions the existence of a zone of chloritic schists, diorite, serpentine, conglomerates, and granite, strongly mineralized in places with iron and copper pyrites, magnetite, etc.

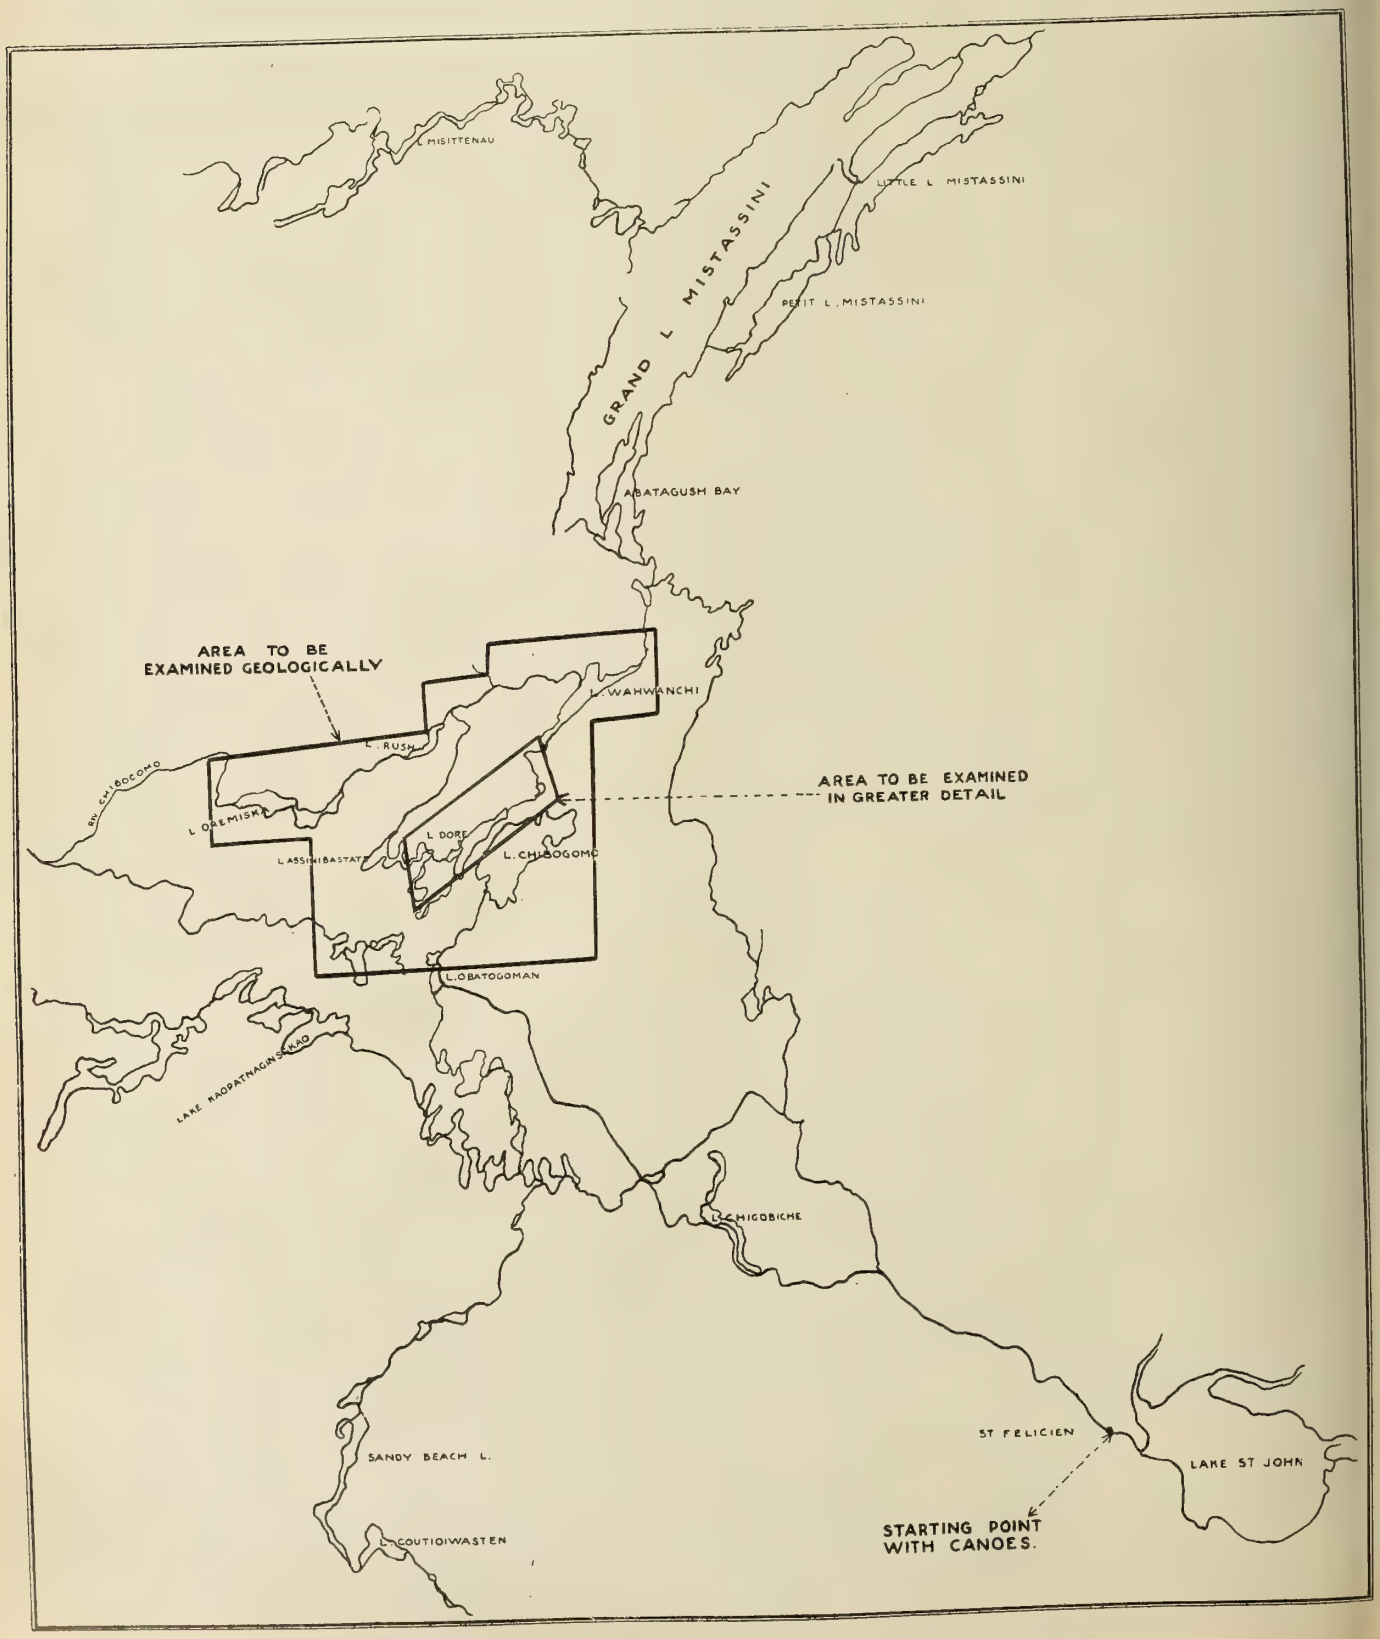
These observations were subsequently confirmed by Mr. A. P. Low, who was in the region in 1885 and who also called attention to the similarity of the rocks to those of the Sudbury district. He states in his report that there are important indications of economic minerals.

In 1897, Mr. H. O'Sullivan, in a report on the country between the Lake St. John and James Bay, mentions that on the portage between Lake Chibougamau and Lake Wacounipi he noticed a compass variation of 166 degrees, caused by some deposit of magnetic iron in the neighbourhood.

Mr. Peter MacKenzie, in 1903, undertook an exploration of the region, from which he brought back good specimens of asbestos and of copper ores.

This was followed in 1904, 1905, 1906, 1907 by further explorations by Messrs. Obalski, Low, MacKenzie, Machin, and Dulieux, with further confirmation of the presence of areas of Huronian rocks and of indications of strong mineralization.

Owing, however, to the lack of transportation, the development of the mineral deposits is handicapped, and the Quebec Government has been strongly urged to take steps to remedy this, either by building a railway into the region, or by granting subsidies towards the construction. But the information that we possess about the region is far from specific. It is the result of explorations on broad lines, and it is not sufficiently detailed to answer such a question as: "Would the Government of the Province of Quebec be justified to either build or subsidize the building of a railroad to develop and work the mineral resources of the Chibougamau region?" The building of such a road would involve several million dollars, and before taking any action in the matter, the Quebec Government has decided to send a commission of geologists and engineers to report on the possibilities and probabilities of the region from a mineral standpoint.



Three commissioners have been appointed: Dr. A. E. Barlow, Mr. J. C. Gwillim, and Mr. E. R. Faribault. The high standing of these three men is a guarantee that the report of the commission will be as authoritative and unprejudiced as possible. Their instructions are to choose their own staff of technical assistants and of miners and labourers, to enquire into the mineral resources of the Chibougamau region, and to advise as to whether or not the Government of the Province of Quebec would be justified in taking steps towards the building of a railway from Lake St. John to Lake Chibougamau.

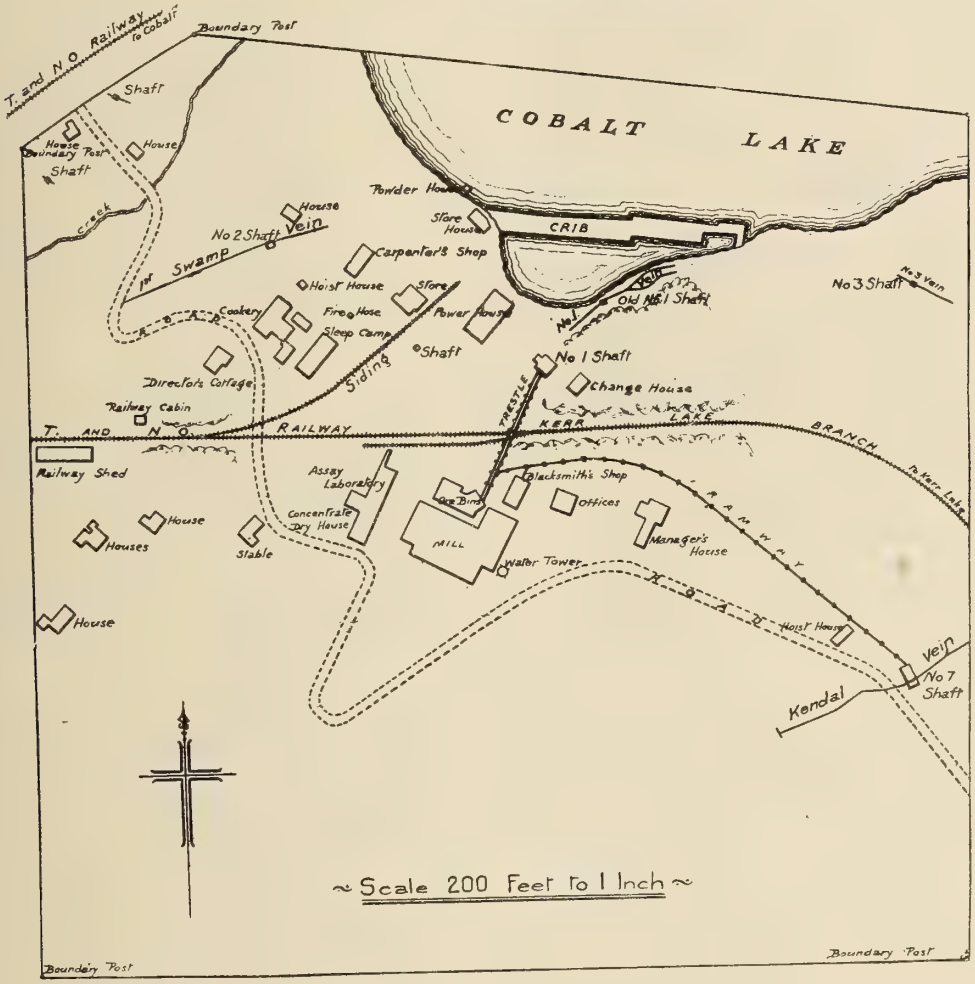
The party will be composed of the three commissioners, each with a technical assistant, and of Mr. Valiquette, of the Bureau of Mines, who will have charge of a topographical and geological party under the direction of the commissioners. Mr. Valiquette will also act as mining recorder, to issue miners' certificates, mining licenses, and record claims. etc., for the conven-

ience of the prospectors in the region. There will, moreover, be ten or twelve men to do the stripping, drilling, and blasting work.

The party will leave Roberval, on Lake St. John, as soon as the state of the rivers will allow, probably at the beginning of June. They will proceed by the usual route by wagon to Portage à L'Ourse, 25 miles; then by water along the Chamouchouan and Chigoubich Rivers, Chigoubich Lake, Nikoban River and Lake, chain of streams and lakes over the height of land, Obatogoman Lake and Lake Chibougamau, a total of 184 miles. They will remain in the field as late as possible.

Irrespective of what may be the findings of the commission, the Government of Quebec is certainly to be commended for this action. It is a wise policy to spend a few thousand dollars to obtain as much information as possible before rushing into an undertaking which will involve four or five million dollars.

THE McKINLEY-DARRAGH-SAVAGE MINES OF COBALT, LIMITED.



(Concluded.)

Savage Claim.

Extent of Mining Operations.

	Year 1909.	Previous.	Total to Date.	Abandoned.
Shafts	180 ft.	508 ft.	688 ft.	140 ft.
Drifts	303 ft.	517 ft.	820 ft.	399 ft.
Crosscuts	28 ft.	403 ft.	431 ft.	403 ft.
Totals	511 ft.	1428 ft.	1938 ft.	942 ft.
Stoping	90 cu. yds.	100 cu. yds.	190 cu. yds.	130 cu. yds.
Trenching	5800 ft.	4000 ft.	9800 ft.

Production of Silver.

Year, 1908,	22,654.82	ounces.
Year, 1909,	62,181.52	ounces.
Total	84,836.34	ounces.

Cost of Operations, 1909.

Insurance, Taxes and Miscellaneous	$ 381.10	
Supplies—		
Miscellaneous	$3,801.09	
Explosives	1,798.64	
Fuel	7,517.71	
		13,117.44
Labour		28,279.55
Total		$41,778.09

Cost of Operating Boarding House and Camp.

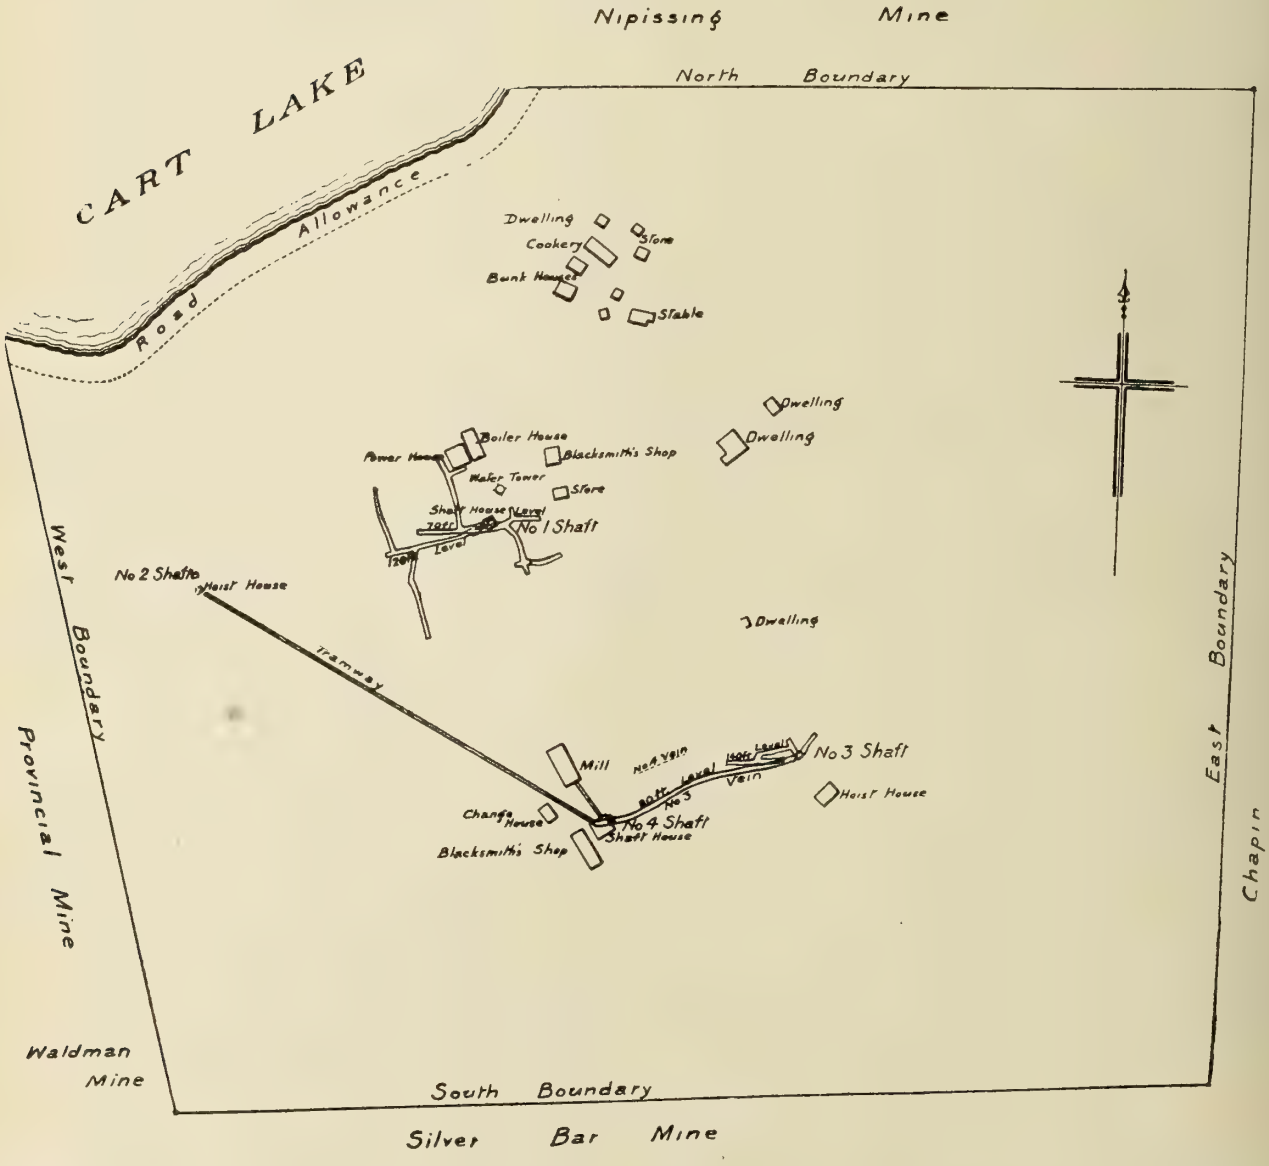
Supplies	$3,937.38
Labour	1,440.00
	$5.377.38

Men have been charged 60 cents per day for bed and board, deductions from pay roll on this account amounting to $4,969.25, which shows a deficit of $408.13, and which latter amount has been charged to labour.

The average number of men employed upon operations has been 33.

It is rather a misnomer to speak of work upon the Savage as Operations, as nothing but exploration and development has been done.

Returns from McKinley-Darragh having provided funds for dividends, plant extensions and operations, we have been able to proceed slowly, and therefore economically, in developing the Savage.



The entire year has been spent in converting this property from a "prospect" into a developed mine, and although the costs have been charged into "operations" they might better be considered as "equipment."

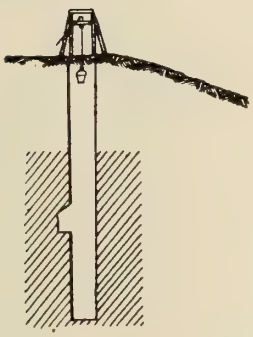
During the past year the importance of the claim as a valuable asset, has developed steadily.

With payable ore in No. 2 Shaft from 40 feet down to 112 feet; No. 3 Vein proven to carry rich values over a distance of several hundred feet; the discovery on the surface of No. 4 Vein carrying nuggets, and

— SAVAGE MINE —

— Plan of Workings —

several other promising veins carrying cobalt, it has gradually become evident that the Savage is worthy of serious consideration as a mine.

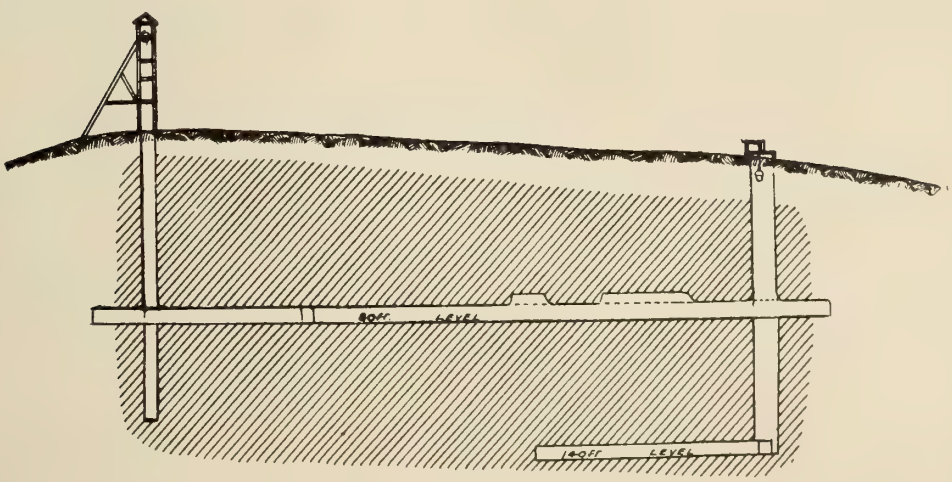


The power plant at present existing upon the property is entirely inadequate for our work, and far greater progress would have been made during the last four months of 1909 if we had had sufficient power available to meet the increased demands made by pumps, drills and hoists.

In fact, during the last three months so great has

— SAVAGE MINE —

— Cobalt, Ontario, Canada —



~ Vertical Section on No 2 Vein ~

~ Vertical Section on No 3 Vein ~

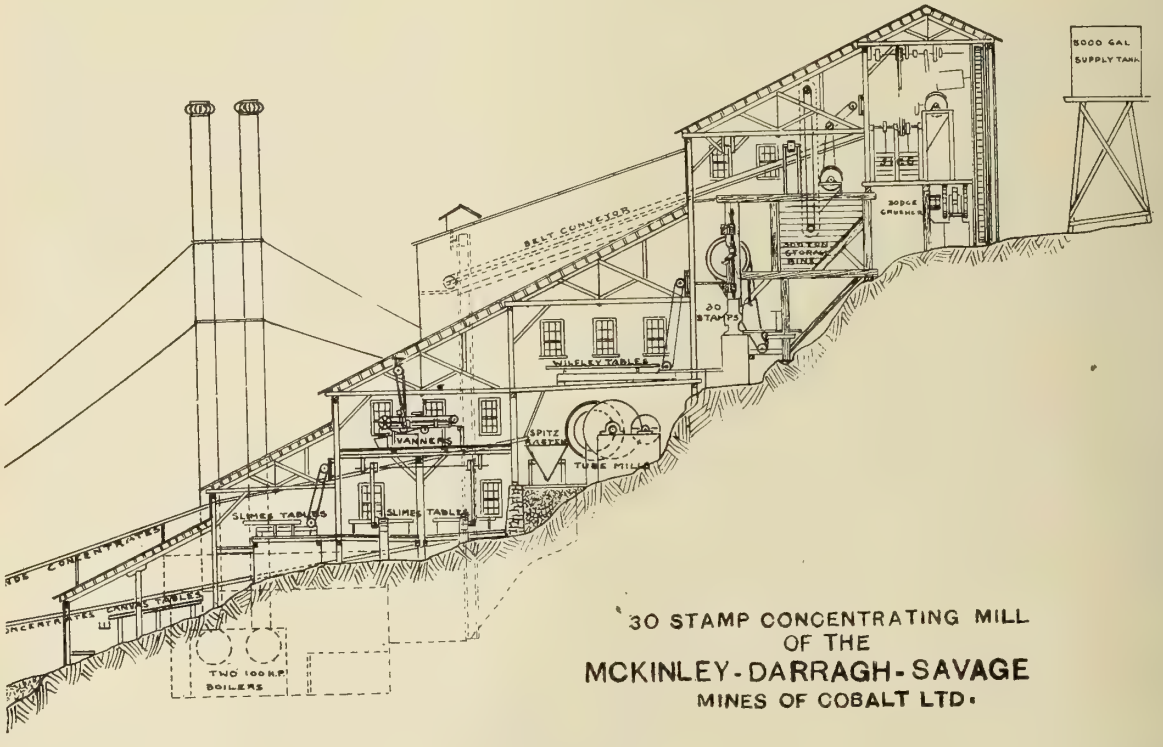
Payable Ore shewn Hatched

been the demand for pumping, that we have been able to operate but one drill.

We have been misled by those companies which propose to supply compressed air and electricity to the camp, as their repeated assurances led us to believe that an abundance of cheap power for all purposes would be available in October and November. With this power supply constantly expected, it has not seemed advisable to spend anything in supplementing our present plant, and the consequence is that we are still struggling along with insufficient power to enable us to push the development of the Savage as it merits. The power supply companies are working steadily upon the installation of their plants and it is probable that there will be a supply of power available in the near future.

With the opening out of the Savage, it became evident that we would be warranted in putting in a somewhat elaborate ore-sorting plant, so that the ore from the various workings could be brought to a central point for treatment. Such a plant has been built and is about completed, the system being as follows

Ore is dumped into bins having a storage capacity of 100 tons. From these bins the ore is drawn out over a grizzley. On the grizzley the ore is washed down and the rich vein matter sorted out and cobbed free of waste. From the grizzley the ore is fed into a jaw crusher and the product from the crusher joins the fine material from the grizzley, both falling into a bucket elevator. The elevator delivers the crushed ore to a sizing screen which makes four products. The finest product from the screen goes to a concentrating table, the next two sizes go to two Hartz jigs. The hutch product from the jigs is elevated to the concentrating table referred to above.



The waste tails from the jigs and from the concentrating table flow out to a dump.

The oversize from the sizing screen is discharged onto a bumping table and is hand picked, the reject going to a dump, there to remain until such time as it will be possible to treat it further in our McKinley-Darragh mill.

The process is illustrated by the "flow sheet," and the details of the ore-sorting plant are shown by the drawings accompanying this report, while the appearance of the plant is shown in the several accompanying photographs.

Our work upon the Savage has demonstrated the fact that only in rare instances do the silver values show upon the surface, and for this reason it is intended to prove up known veins by crosscutting rather than by sinking separate shafts upon each of them.

About six thousand feet of trenches have been dug this year, and altogether about two miles of this work has been done. The result has been the exposure of four veins (one of which carries nuggets at the surface) lying between and extending parallel to veins 2 and 3. Also to the east of No. 3 Shaft a network of cobalt-bearing veins has been exposed.

30 STAMP CONCENTRATING MILL
OF THE
MCKINLEY-DARRAGH-SAVAGE
MINES OF COBALT LTD.

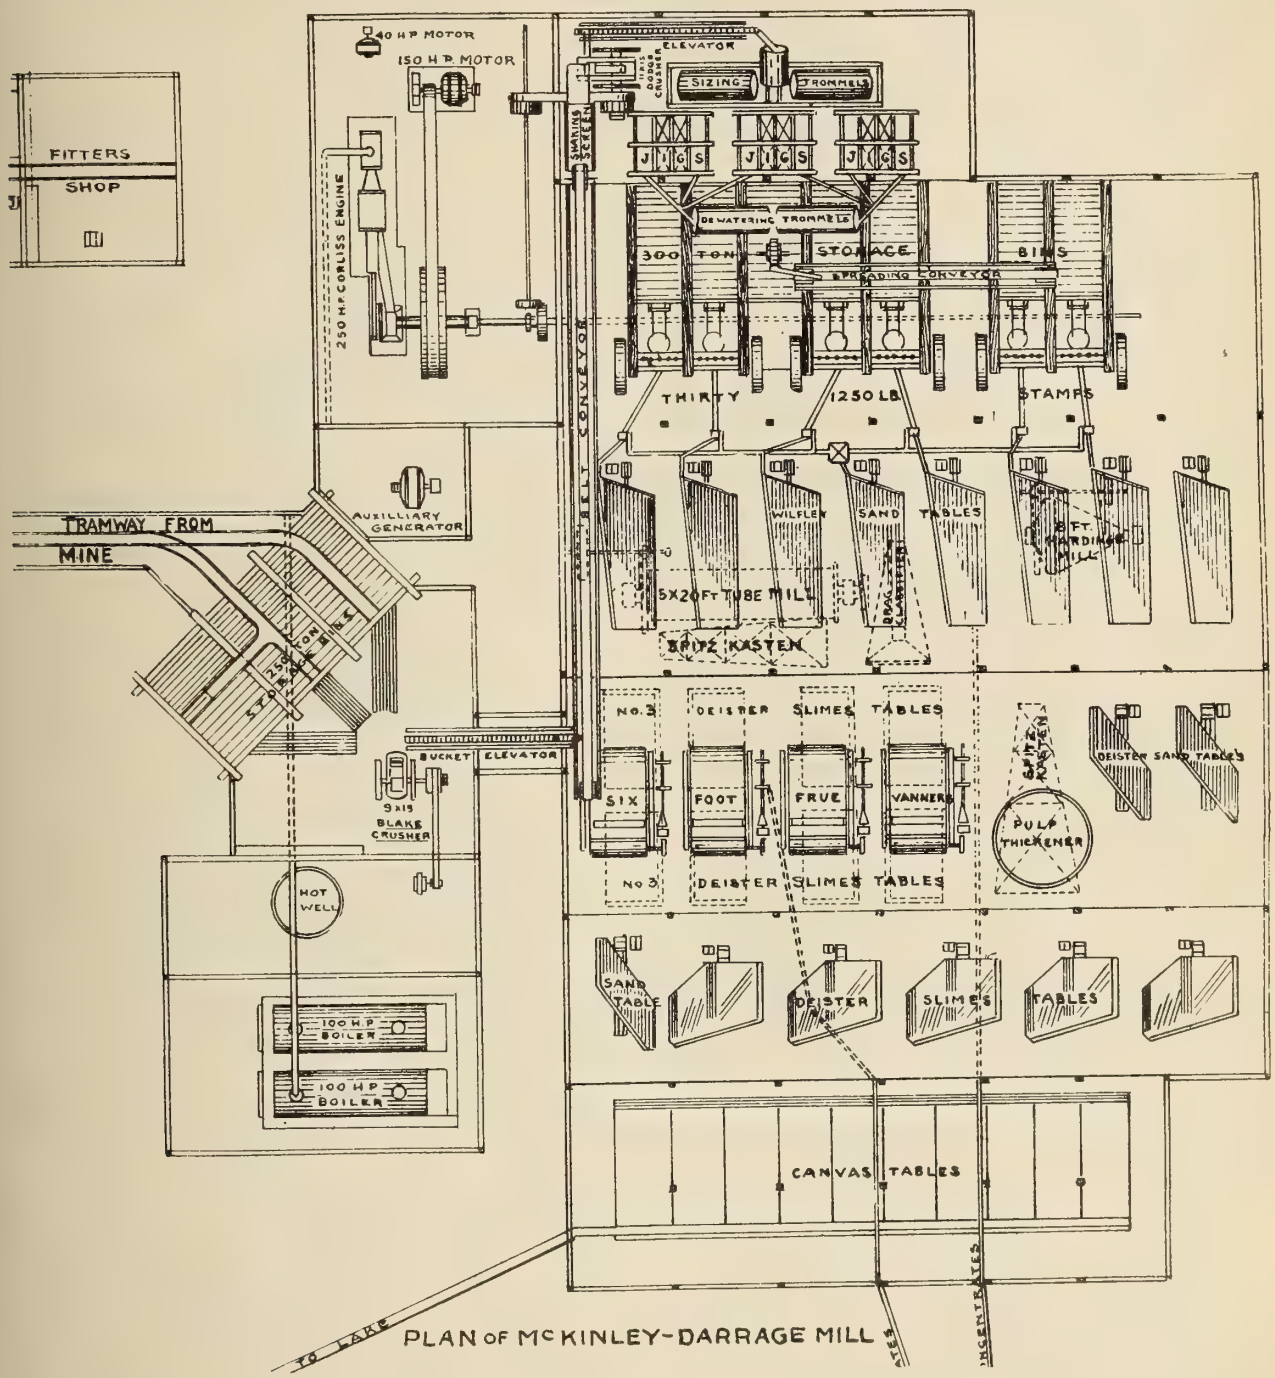
These veins can be reached from the workings on No. 3 vein by means of crosscuts, and all ore and waste rock will be raised through No. 4 Shaft.

This shaft is located at about the centre of the property, on high ground with excellent opportunities for disposing of waste rock and ore, the new sorting plant being fifty feet from the shaft.

A new head gear, hoist house and shop have been erected, and when a supply of power becomes available, it will be possible to develop and mine the property economically from No. 4 Shaft.

The No. 1 workings were abandoned and allowed to flood in January, 1909, as explained in my last annual report. No. 2 Shaft has been pumped out and timbered to a depth of 100 feet, the shaft bottom being 112 feet. A concrete water ring has been installed and a pumping station established at 70 feet, for the purpose of catching up and getting rid of as much water as possible, thereby improving the working conditions in the shaft.

During the summer the Provincial Mine, by means of a diamond drill, proved the continuance of this vein to a depth of 165 feet, and it is my purpose to sink to 200 feet if the ore holds good that far.



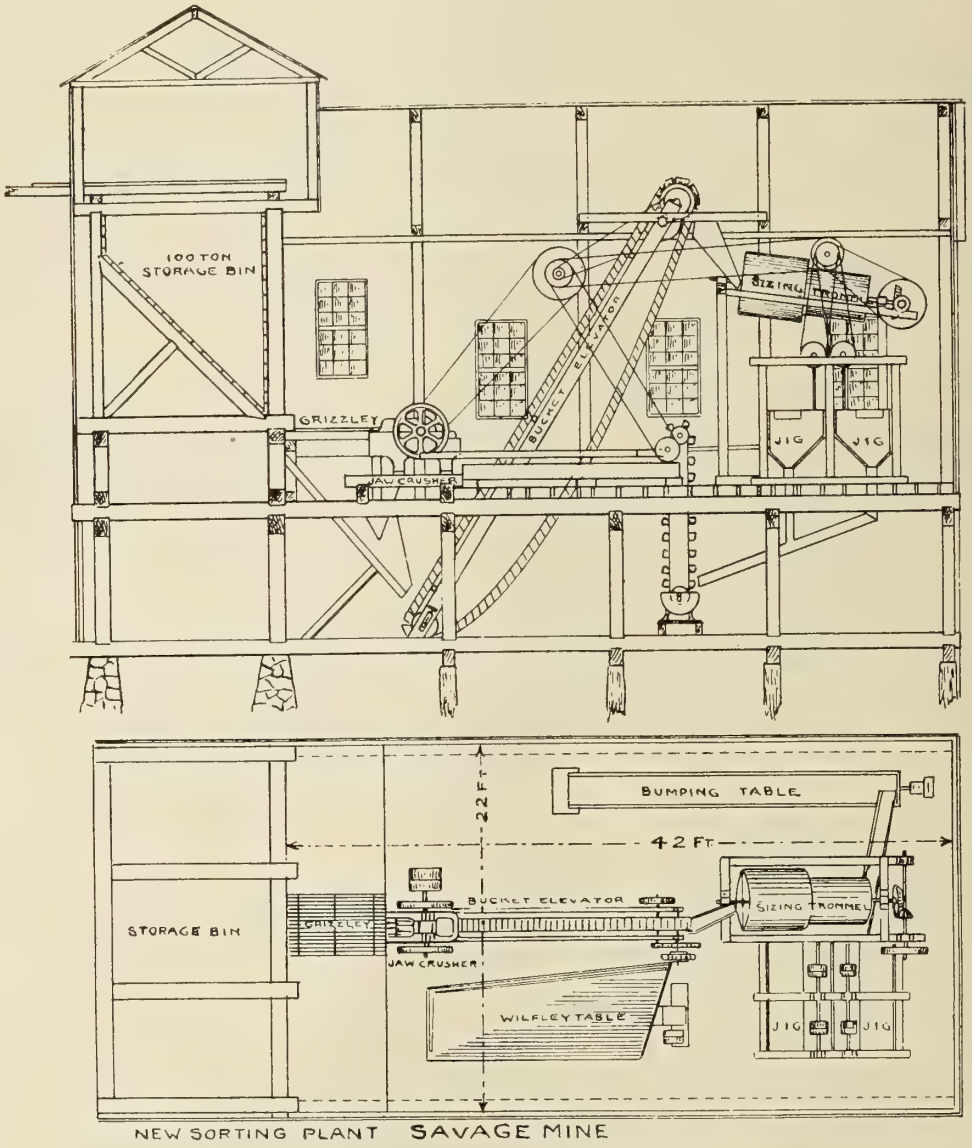
Allowing a distance of twenty feet on either side of the shaft and a vertical depth of 75 feet, I estimate that No. 2 Shaft has developed a reserve which will yield approximately 60,000 ounces, but owing to a lack of knowledge concerning this vein it is not possible to form any accurate conclusions; it is probable that the ore developed will considerably exceed the above estimate.

Pending the completion of the new sorting plant, and the delivery of power, the sinking of No. 2 Shaft has been deferred, and work at present is limited to keeping the shaft pumped out. Meanwhile a trestle has been constructed to connect No. 2 with the new sorting plant at No. 4.

The most important ore body at present known upon the claim is No. 3 Vein.

Sinking No. 3 Shaft, ore was encountered at 20 feet, and for about nine feet the vein was one and one-half inches wide, and carried from 8,000 to 10,000 ounces per ton. From 30 to 75 feet the vein averaged about two and one-half inches in width and carried from 1,700 to 2,500 ounces per ton.

Drifting on the 75-foot level showed ore ten feet to the east of the shaft, at which point the vein ran into an open fissure. No attempt has been made underground to locate the extension of the vein beyond this fissure, but upon the surface it has been located. To the west of No. 3 Shaft the 75-foot level drift has been



connected through to No. 4 Shaft, a distance of 265 feet, and the drift has been carried 20 feet beyond No. 4.

Between No. 3 and No. 4 the vein averages 2 inches in width, and carries approximately 1,800 ounces per ton.

Below the 75-foot level, No. 3 Shaft was sunk to a depth of 130 feet from surface, and a crosscut of 18 feet was driven to pick up the vein. On this level the time being, until sufficient power is available to meet the increased demands for power for pumping.

STOPING.—Sixty cubic yards, stoped from the roof of the 75-foot level drift, represents the only inroad made upon ore reserves during the year.

ORE RESERVES.—The values of the ore reserve in No. 3 Vein can not be accurately estimated, owing to the great variations in the values per ton at different points. From sampling in the shafts and drifts, checked by smelter returns on ore shipped, I believe that I

NEW SORTING PLANT SAVAGE MINE

vein is small (about ¾ of an inch wide) and patchy, though rich in nuggets. There is some silver in the wall rock. A total of 98 feet of drifting was done at this level.

On the night of August 6th, the No. 3 Shaft house caught fire, being completely destroyed, and the burning debris falling down the shaft caused the shaft timbers to burn out above the 75-foot level . After this accident, work on the 130-foot level was suspended, as it was decided not to rebuild the burned structure, but to push the sinking of No. 4 Shaft, making the latter the main hoisting shaft for the workings.

No. 4 has been carried down to a depth of 125 feet, at which level a strata of water-bearing sandstone was cut, and sinking operations were discontinued for the

am conservative in placing a value of approximately 600,000 ounces on the known extent of No. 3 Vein as developed by shafts 3 and 4, and the drifts at 75 and 130 feet. This estimate does not allow for any persistence of values beyond our present workings.

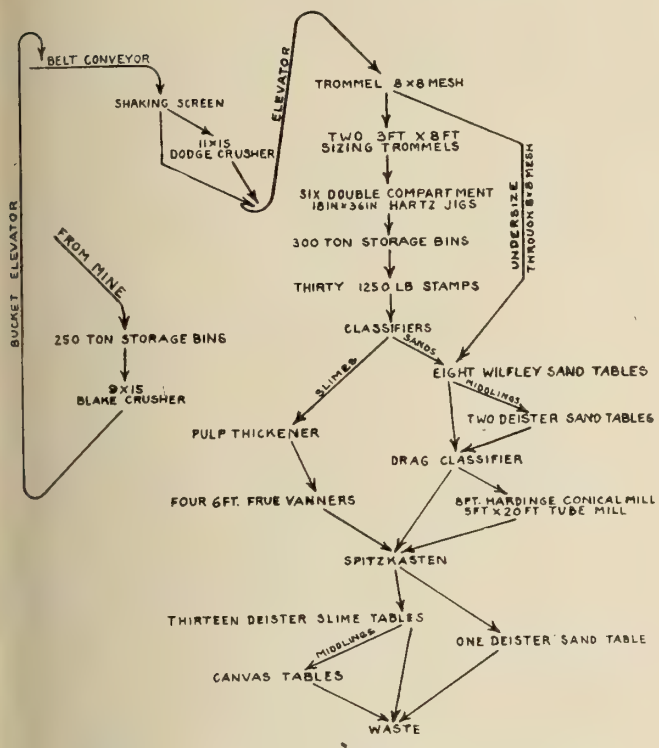
Since the first of the year we have driven a crosscut north from the 75-foot level of No. 3 vein to prove No. 4 vein. At a distance of 44 feet No. 4 vein has been cut. It is 2½ inches wide, calcite and smaltite, carrying 1,000 ounces in silver values.

Allowing 80 feet of backs and a lateral extent of 60 feet will give a reserve of something over 90,000 ounces for this vein. Continuing the above crosscut to the north, at a distance of 26 feet beyond No. 4 Vein, we have also cut No. 5 Vein. It is 1 1-4 inches wide, smal-

tite, and is very rich in silver. No allowance has been made for this in estimating reserves.

Recapitulation of Estimated Reserves.

No. 2 Vein.....	60,000 ounces.
No. 3 Vein.....	600,000 ounces.
No. 4 Vein.....	90,000 ounces.
	750,000 ounces.



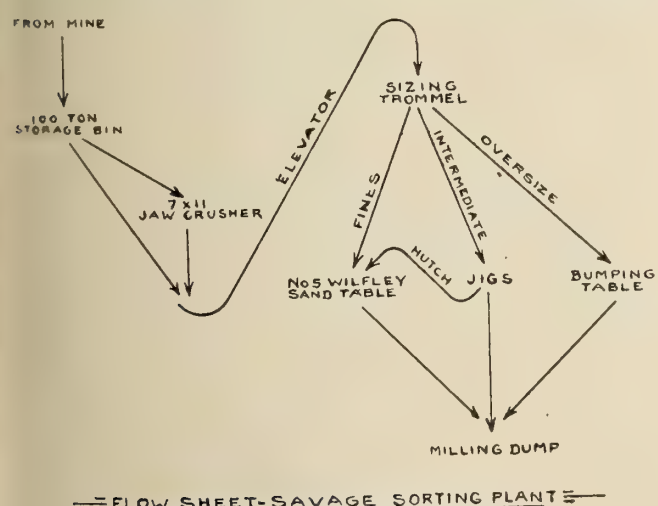


DIAGRAM ILLUSTRATING FLOW OF ORE THROUGH MILL

This is not to be considered as the full measure of the possibilities of the Savage, it represents only the value of that ore which has been fairly well developed.

FLOW SHEET-SAVAGE SORTING PLANT

No. 2 Vein is known to continue to a depth of 50 per cent. deeper than that included in the estimates of ore reserves.

No. 3 Vein has been traced upon the surface for almost twice the length developed underground.

No. 4 Vein has been traced upon the surface for a considerable distance, but has only been prospected at one point underground.

Several other veins, fully as promising in surface showings as were either No. 2 or No. 3, have also been disclosed in trenching.

With these facts in view, one is justified in placing the possible yield of the Savage at a figure greatly in excess of the 750,000 ounces estimated above, and while not venturing any definite figures, I feel that the Savage is destined to become a factor of far greater importance than it is at present.

THE COBALT PROVINCIAL MINE.

(Special Correspondence.)

Many of the readers of the CANADIAN MINING JOURNAL will be interested to know that the Provincial mine, now being operated by a private company, is showing up very well. The principal shaft, near the boundary that marches with the Savage claims, is down 130 feet. Under Government regime this has been sunk 70 feet. At 84 feet a high grade 6-inch vein was encountered. At 100 feet the vein dipped out of the south side of the shaft. Within 50 feet of the No. 2 shaft a rich vein was cut by diamond drill at a depth of 125 feet. This has not yet been cut by the workings. Four veins in all were encountered by the drill. But the best showing was the big calcite vein cut at 125 feet, which showed silver in the core. The shaft was sunk so that this vein could later be cross-cut. The other discoveries were pleasant surprises.

The indications are that the conglomerate here is deeper than in most parts of Cobalt camp. The diamond drill has demonstrated it to be at least 200 feet deep.

Power is now being furnished by the Cobalt Hydraulic. Two Mack drills are in commission.

PERSONAL AND GENERAL.

H. Koppers, by-product coke oven constructor, with offices at Joliet, Ill., has contracted to build 60 by-product ovens for the Woodward Iron Company, at Woodward, Alabama, near Birmingham. The by-product plant will include Koppers' direct ammonia recovery process, and will be built with a capacity to handle the by-products from the plant enlarged to 120 ovens in the future. The coke production from the 60 ovens will be 655 tons per 24 hours. In addition there will be 4,700,000 cubic feet of gas, 4.700 gallons of tar and 9.4 tons of sulphate of ammonia. This is the same type of oven being built so extensively by the United States Steel Corporation. The rapid growth enjoyed by the Koppers' coke oven is evidenced by the following:—Number of Koppers' ovens built and under construction in America, from opening of American office in 1907 to date, 1,376. Total number of Koppers' ovens built and under construction in America and abroad since this type of oven was introduced in 1903, 5,609.

Mr. R. B. Lamb, of the C. L. Constant Company, has retired from that organization to become associated with the Proprietary Mines Company of America, offices at 15 Broad Street, New York City.

Mr. J. B. Comstock, for six years with the Westinghouse Electric & Manufacturing Company at its East Pittsburg Works, and for four years manager of its publication department and printing plant, severed his connection with that company in April to accept a similar position with the P. & F. Corbin Company, of New Britain, Conn.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay, May 17th, 1910.—Since the U. M. W. A. strikers returned to work at Glace Bay, the outputs of the Dominion Coal Company's collieries have increased about one-third, but they are not yet up to the summer maximum. The total production for May will be about 280,000 tons, comparing with 316,000 tons in May of last year. It is anticipated that the June figures will be large, as there is an unusually plentiful supply of labour. The strikers have not all found work at the time of writing, but they are being placed as rapidly as it is possible. Several of the collieries have been placed on double-shift, and the new winnings which the company is undertaking in the Morien and Lingan fields are being vigorously prosecuted. There is every prospect that this summer's coal production in Cape Breton will be larger than ever before, as all the companies are well supplied with men. This state of affairs is rather novel in Cape Breton, and is, of course, due to the importations of men that were made during the U. M. W. troubles.

The mining rates have been fixed at Dominion No. 12 Colliery by agreement between the P. W. A. and the company, and from now on this colliery will rank as an important producer. The surface works on No. 14 will be finished this summer, and No. 15 is now producing about 100 tons per day from development work. No. 16 slopes are being sunk, and other mines are in contemplation. Before long a district where the industries were farming and fishing will become one of the busiest and most prosperous places in the Island.

Owing to the extensive developments which are being undertaken by the three leading industrial concerns in Cape Breton, namely the Dominion Steel and Coal Companies and the Nova Scotia Steel & Coal Company, there has been a marked restoration of business confidence. The coal-steel "merger" has put an end to the protracted friction between these two mutually dependent enterprises, and now that the U. M. W. trouble is past, there seems every reason for optimism for the future of the coal and steel industries of Cape Breton.

The Colliery Relief Societies.—The Nova Scotia Government has just enacted a Workmen's Compensation Act, but they have excepted from its provisions those coal companies at whose works relief societies are established, on the understanding that the scope and usefulness of these societies are to be enlarged. The president of the Dominion Coal Company, together with the general manager, lately met a deputation representative of all the relief societies at the mines of the Dominion Coal Company and explained to them the desire of the company to give effect in the very fullest manner, to the evident wish of the Government, that adequate provision shall be made for the victims of industry throughout the province. The president expressed his desire to see a scheme of benefits arranged which should be second to none in Canada, and announced that the company would contribute equally with its workmen to the cost of any scheme which should be decided upon. No definite plan was presented, as the meeting was purely of a preliminary character, advantage being taken of Mr. Plummer's presence in Cape Breton to enable him to meet for the first time a committee of the workmen at the mines. Mr. Plummer and Mr. Butler both emphasized the necessity of commencing properly and with an adequate scale of contributions. It has been suggested that the sole desire of the Coal Company, in advocating an extension of the relief societies, is to enable them to escape the cost which a Workmen's Compensation Act would bring upon them, and one newspaper irresponsibly stated that the cost to the Dominion Coal Company alone under such an Act would be $200,000 per annum. This newspaper has absolutely no grounds for such a statement. The yearly cost for death claims, under the scale proposed by the Nova Scotia Act, would not exceed $25,000 to $30,000 at the highest computation. This would leave say $175,000, as the cost of non-fatal accidents. The average maximum of the Coal Company's employees is about 7,500 men. The Act provides for weekly payments as compensation for injury, which amount to about half of the wages which would be earned at work. A little calculation will show that in order to incur such an enormous bill for compensation, would mean that every employee of the company would lose one month out of every year by reason of disability to work caused by injury. There is surely no reason to point out the absurdity of such an assumption. As a matter of fact, if the tentative proposals now before the relief societies are put into effect, it is doubtful whether there will be much to choose on the score of cost between the company's share of the expenditure of the relief societies, or the amount it would have to disburse for injuries under a Compensation Act. But any person who has had any experience with the clerical work which is associated with the actual operation of a Compensation Act, the dissatisfaction it occasions, the litigation and bickerings between employers and employees, between doctors and lawyers, added to the insufficiency of such a law to relieve many of the most pressing cases of need, will appreciate the desire of any corporation to be relieved of its operation, even if it involved a greater expenditure in money. Owing to the peculiar ideas which many insurance companies hold as to the dangers of a miner's life, men engaged in this trade are unjustly deprived of insurance facilities which are open to men engaged in other trades, many of them, if the insurance companies only knew it, far more dangerous to life and health than that of a miner. The miner in his individual capacity cannot insure against accident and sickness, except through some form of mutual friendly society, and the Compensation Act does not adequately meet his needs alone. This fact is thoroughly appreciated by the miner. The relief societies have in the past been the miners' sheet anchor, and their future usefulness bids fair to increase as the years go on. The interests of the employer and the workman are identical in these societies, malingering is checked, provision is made for sickness and accident also, the extent of the relief disbursed increases automatically with the extent of the family that is dependent, the less onerous demands of the single man help out the needs of the married man, the provision for widow and children is disbursed in small sums, which is often a preventative of misuse and waste. Those who are advocating the enlargement and consolidation of the relief societies at the collieries have a more intimate knowledge of the needs of the miner than either the legislature or the press, and are building wisely and well.

ONTARIO.

Cobalt, May 18th, 1910.—The fight for the control of the Beaver was ended at the annual meeting, when the present management was sustained. Another car of rich ore has been shipped from the property, which will raise sufficient money to carry on the work for some time to come. The veins underground are looking well and the management could ship more ore if they desired, but their object is to thoroughly develop the property and block out reserves.

The Fisher Eplett, which adjoins the Beaver, and is one of the La Rose holdings, is now being prospected, twenty-five men having started trenching. No work has been done on this section of the La Rose holdings for over two years, but the good ore being found on the Beaver has encouraged the management to continue their prospecting.

The official figures for the production of the Cobalt camp for the year 1909, published by the Bureau of Mines, Toronto, show a total output of 25,835,983 ounces of silver. The estimated production was only 24,000,000 ounces, so that the returns much exceeded expectations. The production from South Lorraine amount-

ed to 144,953 ounces shipped from the Keeley and Wettlaufer, the latter company having been the largest contributor.

On the Yorke-O'Brien lot in the Gillies Limit, the vein was cut in a crosscut from the 100-foot level. It shows several inches of calcite with native silver, and will probably assay in the neighbourhood of 500 ounces per ton. The shaft has been continued a depth of 150 feet, and a crosscut from this level will be run to intercept the vein. Work has been stopped until air from the power companies can be obtained, as the property is equipped with only a small steam plant. The vein recently cut is a continuation of the one worked on the Red Jacket. The latter company, however, closed down shortly after its discovery and no work has been done since. Trouble among the owners is said to be the reason and a few days ago, the supplies of all sorts were sold to satisfy a debt due one of the banks.

Toronto men who are interested in the Bartlett property in Gowganda are endeavouring to get things running again. It is stated that McLaughlin and McIntyre, the original owners, have contributed 350,000 shares, to be placed in the treasury and sold for 25 cents. A considerable sum of ready money has also been raised, in order to commence work as soon as possible. The property is equipped with a splendid plant, including a twelve-drill compressor and a complete machine shop. It is understood that the whole thing cost in the neighbourhood of $125,000 by the time it was installed. Only a small section of the company's holdings has been prospected and it controls a large acreage in the richest section of the district. One shaft was put down about 100 feet with a small amount of crosscutting accomplished, when the company had to close down for lack of funds. The shipments from Gowganda last winter proved the district to be worthy of serious consideration, and are largely responsible for the increased public confidence. The Millerett was the heaviest shipper, and it already has another carload on hand. The development work now being accomplished is proving up the ore bodies in a satisfactory manner. At the Reeves Dobie, there is a considerable body of ore blocked out above the 80-foot level, and next winter will probably show a material increase in its shipments. The shaft is down 160 feet and will be continued to the 250-foot level. At this point a crosscut will be run to cut the vein. The crosscut from the bottom of the shaft of the Miller Lake-O'Brien has cut the vein which shows good ore. Last winter an English syndicate took an option on the Morrison property, which has one of the most sensational surface showings in the whole district. They agreed to spend $100,000 in proving the claim, but owing to the early breakup, it was unable to get its machinery in. On this account the option has been extended for a further period of six months.

For the past week or so bush fires have been causing considerable uneasiness, and the plants of some of the outlying properties had a narrow escape from being burned. The lack of rain has made everything very dry, and the fires were probably started through carelessness.

The best ore in the history of the Rochester is now being taken out of that property from the vein opened up a short time ago. It is believed that only the apex of the ore shoot has been cut, as the ore is much better in the bottom of the level. The vein varies up to five inches in width and is exceedingly rich. The shaft will be sunk an additional 75 feet to the 150-foot level, and from that point a crosscut will be run to cut the vein. A considerable amount of ore has been bagged, and it is probable that a shipment may be made in the near future.

The Nipissing Central Railway, the electric road between Cobalt and Haileybury, has now been running for some time, and has proved a great boon to these two places. As an outcome of the road, several quite important settlements have sprung up along the right of way, and these are growing rapidly. As an evidence of the business done it may be stated that during the first nine days the cars were running, they carried 30,000 people. It is probable that this summer the road will be extended to Liskeard.

Conditions at the Cobalt Lake Mine continue to be very satisfactory, and in the drift from the bottom of the winze there are thirteen stringers of ore across the face. A crosscut is being run to intercept the Pellatt and Morrison veins and should these have good values at this depth, the mine will have a very considerable ore reserve. Two or three cars of screenings are now ready for shipment and will be sent out shortly.

A car of ore has recently been shipped from the Provincial Mine for the Ontario Government. This ore was lying in the ore house at the time the property was sold, and was taken out when operations were carried on by the Government. A short time ago the new owners of the property found a high-grade vein near the boundary of the Savage Mine.

Two new veins have already been found on the Nipissing by the gangs employed trenching. They have been stripped for about twenty feet, and although narrow, contain high grade ore.

Several parties of Government geologists have started for the different districts of Northern Ontario, where they will thoroughly explore and map the country. Professor Miller, with his assistants, will work out the geology of the Porcupine district, while another party will examine the lignite deposits near the Mattagami River. An engineer recently returned from there, states that the lignite is of inferior quality, but suitable for domestic purposes. The deposits, however, cannot be utilized commercially, until railroad transportation is available. Other parties from the Provincial Department, are being sent to the Sturgeon Lake, Port Arthur and Rainy River districts.

The Temiscaming and Hudson Bay has declared another dividend of 300 per cent., or $3.00 per share. This will be payable on May 25th and makes a total of $12 per share already paid for 1910.

The condition of the La Rose is steadily improving, and the latest favourable development is the opening up of a new ore body on the No. 11 vein of the Lawson. This vein was cut on the fifty-foot level and shows altogether about ten inches of high-grade ore. This vein was discovered last year on the surface, and has been traced for nearly 1,000 feet. This makes the second vein on the Lawson giving high values at any depth.

The O'Brien is now shipping silver bullion, more or less regularly, to the Bank of England. The last shipment amounted to 17.116 ounces, bringing their total shipments of bullion up to 85,366 ounces.

The new concentrator at the Nova Scotia has commenced running, although it is not yet operating to its full capacity. The Silver Cliff mill has been running for some time and has made its first shipment of concentrates amounting to 20 tons. The Trethewey concentrator is also ready, and part of the machinery has been running. When these new mills are operating their output of silver will show a material increase.

The question of compressed air power is still unsettled, as at the present time neither of the two companies is in a position to make deliveries. The Mines Power started some time ago, but so far its air service has not been satisfactory, due to frequent interruptions. Such power as was delivered was very good, the air being clean and dry and maintained at a constant pressure of about 105 pounds. The company, however, has had all its generators at the Matabitchouan plant burned out, and although it is running sufficient to supply electric energy to its customers, it is still unable to run its compressors. The management expects to be in a position to turn on the air again on May 22nd, and should then be able to proceed without any more serious interruptions.

The Hydraulic Company has the plant at Ragged Chutes nearly completed, and should be able to deliver power in a short time.

Porcupine.—Due to poor transportation facilities, very little is being heard of this district, but the reports that do come are very satisfactory. The Miller Company has obtained assays from the big vein that run as high as $238.00 per ton. These samples were taken across the vein, but doubtless in the richest portions. The Timmins are stated to be putting up a test plant of 15 tons capacity, to treat some of the ore produced in development work.

The treatment will consist of amalgamation and cyaniding, and the plant will give the owners a much better knowledge of the value of the ore than would be possible by sampling. At the Hollinger, the plant is now running and a force of 90 men is employed. In the crosscut from the No. 2 shaft at the 60-foot level, assays of $347.00 per ton were obtained. Free gold has been found in the south of Shaw Township, and a few days ago three claims in that vicinity were sold for $20,000. It is possible that before the season is over, several of the camps may run short of supplies, as the number of men employed is greater than was anticipated.

Kenora, Ont.—At a meeting of the Prospectors' and Mine Owners' Association of the Kenora Mining Division, held May 11th, Mr. A. L. Parsons, lecturer in Mineralogy of the Toronto University, addressed the members and gave them a very interesting little lecture upon the methods which should be employed by the ordinary prospector in his search for mineral wealth, exemplifying by means of one or two incidents from his own experience the necessity for the prospector not to confine his energy to the examination of the rocks for one thing only, but rather to be in a position to recognize any ore of commercial value with which he might come in contact. At the close of his lecture a hearty vote of thanks was tendered to Mr. Parsons for his courtesy in meeting the members of the Association.

This district is at present becoming somewhat excited over the reported finds of tin in the boundary country, some thirty miles west of Kenora. The main deposits from which it is claimed this tin is obtained varies in width from 300 to 1,200 feet, and has been staked for a distance of 8,000 feet. This ore which appears to be very heavily mineralized, carries a larger percentage of sulphur and requires thoroughly roasting before any results can be obtained by fire assay, but under this treatment from the results obtained so far, it seems to promise very well. The West Hawk Lake district comes to the front this time with some samples of pyrrhotite which has been located on the contact. The vein is eight feet wide on the surface, and has been traced and staked for a distance of two miles. No direct analysis of this ore, giving its percentage of nickel, has come to hand; but the parties interested are making arrangements to have this ore thoroughly tested so as to be in a position to place their holdings upon the market. The Star Lake properties are still being developed and the holders of these properties are expecting very shortly to announce the closing of a deal with the syndicate, who will operate the whole group of claims.

The work is still progressing of opening up the Alley Island copper property, whose discovery was reported some months ago. This is one of the few properties in which copper occurs native in any quantity. The action of the Government in sending up a geologist to correct several inaccuracies in the existing geological maps of this district, and to make a further report on the geology shows that they are at least becoming awakened to the importance and the large possibilities of this territory.

BRITISH COLUMBIA.

Available information relative to the progress of mining in the province during the four expired months of the current year indicates that ore production has been on a larger scale than for the corresponding period of any previous year. Complete returns are not obtainable before the close of each year, but for the chief ore-producing districts the statistics published weekly by the Nelson "Daily News," afford a general idea of the situation. These show that production for the year to the end of April, was as follows: For Boundary district, 636,191 tons; Rossland, 85,441 tons; Slocan-Kootenay, 111,431 tons; total, 833,063 tons. The corresponding figures for 1909, were: Boundary, 491,489 tons; Rossland, 80,346 tons; Slocan-Kootenay, 60,815 tons; total, 632,650 tons. This comparison shows an increase in the tonnage of the district named of nearly one-third. Of the 200,000 tons increase, 145,000 was from Boundary district mines, 5,000 tons from those of Rossland, and 50,000 from those included under the head of Slocan-Kootenay. The increase in tonnage of ore reduced at the several operating smelters of the districts under notice, is evident from the next following figures:

At Smelter of	Smelted during First Four Months of 1909.	1910.
Granby Company	313,223 tons.	427,263 tons.
B. C. Copper Company	140,505 tons.	144,960 tons.
Total for Boundary	453,728 tons.	572,233 tons.
Consolidated M. & S. Co.	117,502 tons.	169,622 tons.
Total	571,230 tons.	741,845 tons.

Of the increase of 170,000 tons smelted, 114,000 was credited to the Granby Company, 4,000 to the B. C. Copper Company, and 52,000 to the Consolidated Company. The tonnage of ore milled during the same periods was, in round figures, 61,000 tons in 1909, and 91,000 in 1910, the latter showing an increase of nearly 50 per cent.

Beside the increased production of lode mines, there is good reason to look for an equally satisfactory increase from both placer gold and coal mining, operations in connection with both of these being on a larger scale than in 1909. It would appear, therefore, that if nothing occurs to check progress and interfere with production at present rate, the output of minerals should this year prove to be the largest in the history of mining in British Columbia.

CARIBOO.

Barkerville.—Placer gold mining for the season has been fairly commenced. Mr. John Hopp's hydraulic mines, the Mucho Oro on Stout's gulch, the Forest Rose on the east Branch of Williams Creek, and those on Lowhee and Mosquito Creeks, are being worked; provision having been made for an increased supply of water for gravel-washing, and the prospects for the season being favourable, there should be a larger quantity of gold recovered from these mines than in previous seasons. Other hydraulic mines are being operated, though not on so large a scale as those of Mr. Hopp.

Quesnel Forks.—In Quesnel division the most important work in progress is that of dam and ditch construction for the Philadelphia company, represented by Mr. Howard W. DuBois. Between 200 and 300 men and a number of horse teams have been employed in connection with the preparations for the development of a large hydraulic mine at Twenty-Mile Creek, on Quesnel River, about 20 miles below Quesnel Forks. Construction of a ditch and flume to carry 6,000 to 7,000 miner's inches of water from Swift River to Twenty-Mile Creek, is being expeditiously proceeded with. The undertaking is a big one, the whole enterprise involving an expenditure stated to be estimated at about $1,500,000. Mr. John B. Hobson intends to hydraulic gravel on some of his placer-gold leases and looks for profitable returns from the season's operations.

EAST KOOTENAY.

Placer Gold.— On Wild Horse Creek the Invicta and Nip and Tuck properties are again being hydraulicked. On Perry Creek operations have been commenced with one large hydraulic plant, and it is intended to again use the steam shovel, put in here several years ago, to handle the gravel. On upper Moyie River and on several other streams in Fort Steele mining division, small hydraulic plants are at work.

Lead-Silver.—The St. Eugene is regularly maintaining an output of lead-silver concentrates and shipping same to the Consolidated Mining & Smelting Company's smelter at Trail. The same company is working the Sullivan group, near Marysville, and has this year shipped to Trail about 4,000 tons of ore from that mine. The Aurora, situated across Moyie Lake from the St. Eugene Mine, will send ore to the Alice Mine concentrator near Creston; it is expected that by this arrangement it will be found practicable to make a marketable product at a cost which will leave a margin of

profit to the mine-owners. Preparations are being made to ship ore from the Society Girl, on which ore has been cut by a long crosscut tunnel.

Coal.—The Crow's Nest Pass Coal Company looks for conditions being favourable for larger production at its mines henceforth. An adequate supply of railway cars for hauling the coal away has been promised, and arrangements have been made with the Great Northern to take about all the coal the company shall find it practicable to supply that railway with. The C. P. R. Mine at Hosmer, and the mine at Corbin, owned by a Spokane company, are both being regularly worked; the prospects for these comparatively new mines are that their output will be larger this year than last.

WEST KOOTENAY.

Ainsworth.—In Ainsworth camp proper there is not much being done at present, but those directly interested are endeavouring to arrange for an early resumption of work at both the Highland-United and Krao properties. The Blue Bell, across Kootenay Lake from Ainsworth, is not now being worked; the manager, Mr. S. S. Fowler, has gone to Europe with the stated purpose of meeting the larger shareholders of the French company owning the mine and informing them what plant and machinery are required to allow of the big mine being worked to advantage. There is much lead-zinc ore accessible, but hoisting and pumping machinery is required to make this available for milling. On the south fork of the Kaslo Creek the Cork Mine is to be worked again this season, besides several smaller mines also on that creek. The Whitewater group has resumed shipment of concentrates, some 10,000 tons of ore having been milled during the four expired months of the year; both lead-silver and zinc-silver concentrates are produced. The Utica and Wellington Mines will be producers again this year.

Slocan.—The rebuilding of several bridges, so damaged some time ago that no trains have since been run over the Kaslo and Slocan Railway beyond McGuigan, has been ordered, so transportation facilities for mines near Sandon will ere long be improved. Recent developments at the Rambler-Cariboo Mine are the most important in recent years at that property. The finding of valuable shoots of silver-lead ore on the 900 and 1,000-foot levels had added considerably to the producing capabilities of the mine. The annual meeting of the Rambler-Cariboo Mines, Limited, will be held at Kaslo in June, and it is expected the report then to be presented will be the most favourable since the mine's dividend-paying periods of years ago. Shipments from the Richmond-Eureka mines, owned by the Consolidated Mining & Smelting Company, were in excess of 1,600 tons for four months to April 30th. With the melting of the snow working conditions should be favourable to an increased output. The Slocan-Star and Ruth-Hope groups, both in the vicinity of Sandon, will contribute substantially to this year's total output. The concentrating mill at the former will probably be operated again after having been idle for several years. Above Cody Creek, the Noble Five, Surprise, Reco and Sunset, are all being worked. About Slocan Lake there is also encouraging activity. The Mollie Hughes, near New Denver; Standard, Van Roi, and Hewitt-Lorna Doone group, in Four-Mile Creek camp; Eastmont (Ellis Silver Mining Company) at Ten-Mile Creek, and Ottawa, on Springer Creek, all tributary to Slocan Lake, are also being worked, with good prospects for an appreciably large total production of ore this year.

Nelson.—Near the city of Nelson the Granite-Poorman group is keeping its gold stamp mill running continuously, and at the Silver King is shipping silver-copper ore to Trail. The latter has this year sent out about 1,300 tons by the end of April. The acquirement recently of the old Molly Gibson Mine by the Consolidated Mining & Smelting Company, leads to the expectation of an early resumption of production there, though it is not yet known whether the mill put in by the La Plata Mines, Limited, which worked the mine during two years, will again be used for concentrating purposes, or all the silver-lead bearing ore mined be shipped crude to Trail. In the southern part of Nelson mining division, mining gives promise of improvement, there being work in progress in Ymir, Salmo, Sheep Creek and Erie camps. This year's shipments from the Yankee Girl, at Ymir, had, by the end of April reached a total of rather more than 2,200 tons. The Emerald, near Salmo, has shipped about 1,100 tons of lead ore in 1910. The Queen and Nugget, at Sheep Creek, are both producing steadily, the former having this year milled about 7,000 tons at its 20-stamp mill, and the latter 2,000 tons at its 4-stamp mill. Development work in the Mother Lode, another Sheep Creek mine, is stated to be resulting satisfactorily and arrangements have been made for operating power drills in this mine in place of hand drills. Gold is the chief valuable metal in Sheep Creek ores.

Rossland.—The War Eagle Mine, of the Consolidated Mining & Smelting Company's Centre Star group, is reported to be in a position to supply during several months a fairly large tonnage of ore containing a higher average of gold than usual. There has not been any development of importance in connection with the exploration of the Le Roi by diamond drills, no large body of ore of good grade having yet been found. Fire has destroyed the head works at the No. 1 mine of Le Roi No. 2, Limited, but as all the ore has for some time been hoisted through the company's Josie shaft, production will not be interfered with. The loss, which is partly covered by insurance, is reported to have been about $10,000, this including head-frame and electrically-operated hoist. The year's total receipts of ores and concentrates at the Consolidated Mining & Smelting Company's works at Trail to May 7th, are stated to have been nearly 180,000 tons, as compared with 125,000 tons for the corresponding period of 1909.

Boundary.—The tonnage of ore shipped in 1910 to May 5th has reached a total of 660,500 tons; of this, 450,000 tons was from the Granby Company's mines, 145,500 tons from those of the B. C. Copper Company, and practically all the remainder from the Consolidated Mining & Smelting Company's Snowshoe Mine. The Granby Company's total gives an average output of a little more than 3,600 tons for each of the 125 days of that period. It is reported that the B. C. Copper Company expects to soon have enough men to admit of its mines and smelter being worked to ordinary capacity. Numbers of the men who lately refused to continue working with non-union men have left the district. Two of the three blast furnaces at this company's smelter at Greenwood, are being enlarged. New York news is to the effect that 25,000 tons of ore from the New Dominion Copper Company's mines will be smelted at Greenwood, results to be taken as a guide in making permanent arrangements between the two companies for the reduction of Dominion Company's ores.

Similkameen.—Further development of the Hedley Gold Mining Company's Nickel Plate Mine is in progress, and additions are being made to plant and machinery at the company's 40-stamp mill. The V. V. & E. Railway, constructed by the Great Northern, is being operated to Princeton, and the further extension into the Tulameen country is in hand. Coal from the Vermilion Forks Mining & Smelting Company's Princeton colliery has been shipped over the new railway.

Nicola.—Coal mining operations are gradually assuming larger dimensions in Nicola Valley district. The Nicola Valley Coal & Coke Company is steadily enlarging its output. Last year this company mined about 70,000 tons; production for the four expired months of this year must be well on to a similar total. Several other companies are preparing for a regular output.

Coast.—The reported sale of the Dunsmuir coal mines to Mackenzie & Mann interests, and some local excitement relative to Portland Canal mineral claims, are the chief features connected with mining in the Coast district. The Portland Canal Mining & Development Company is the only organization that has yet done much actual mining on its property in the new camp, though two or three others have also driven some tunnels.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The Dolcoath's new shaft has now been completed. It is three thousand feet deep, vertical from the surface, is lined throughout its entire depth with nine inch brick, and is seventeen feet nine inches in diameter—inside measurement. It is considered to be the finest piece of work of its kind in the West of England, and numerous mining engineers and others have visited it during the progress of the work. The contractors (Messrs. Piggott) have opened up the entrance to the north and south headings at the bottom, or five hundred fathom level, and are now engaged sinking below this point in order to make a sump for this new shaft, after which they will continue to drive from the south heading to intersect the Dolcoath lode.

At the Home Office April 21st, Mr. Churchill received a deputation consisting of the Parliamentary Committee of the Trades Union Congress, the Miners' Federation, Durham and Northumberland deputies and enginemen and the Wind Enginemen's Federation, who urged him to embody in a Bill some of the recommendations suggested by the Royal Commission on Accidents in Mines.

Mr. Churchill congratulated the deputation upon the steady progress made in adapting the whole industry to the conditions of the Eight Hours Act. The Home Office would give effect to the view that pump miners' hours were not applicable to bona fide hauliers. The great bulk of the recommendations of the Royal Commission required legislation to give effect to them, and at present great delay hung over all legislation. In addition, the Commission had not completed its labours and it would be better that a Bill for regulating the work of coal mines should cover the whole ground. He thought the inspectors should be strengthened, but the difficulty of money came up. There was to be a conference with mine owners at the end of May with a view to ascertaining how best to improve and systematize rescue apparatus and working. The Treasury had sanctioned the provision of a testing station, and they were now looking for a suitable site. In conclusion, Mr. Churchill said that when the Bill came to be framed, if he was responsible for the task, he should confer not only with employers, but with representatives of the men and make sure that the measure did contain practical points.

At the special meeting of the Coal Conciliation Board of South Wales and Monmouthshire, held at Cardiff, April 8th, the clauses of the new agreement were discussed, and steps were taken to insert the terms agreed upon which the workmen have balloted. No serious difficulty arose during the discussion and the agreement was duly signed by the representatives of the owners and workmen, with the exception of Mr. C. B. Stanton, miners' agent for Aberdare, who stated he could not sign because the majority of the men in his district had voted against the acceptance of the new terms.

The result of the ballot of the miners employed in the South Wales coalfield was an overwhelming vote in favour of the signing of the new agreement. The official figures were:—

For the agreement	97,273
Against the agreement	34,963
Majority for	62,310

The ballot thus brings to a satisfactory and peaceful settlement the protracted negotiations which have been in progress between the representatives of the coal-owners and the men since December last. The new agreement is for a period of five years.

Manchester, Friday, May 13th.—One hundred and thirty-seven miners lost their lives in an explosion in the Wellington coal mine at White Haven. Rescue parties succeeded in saving four men, but fire has broken out in the works, leaving practically no hope for those who are still entombed.

Throughout the day rescue parties made considerable progress at the mine, but their work was stopped by the collapse of the roof.

It is curious that a colliery warning was published in many of the newspapers in the mining districts of the Kingdom yesterday to the effect that an unusually high barometric condition rendered fire-damp explosions extremely probable, and that underground workers ought therefore to be on the alert. The barometer reached the highest reading in the White Haven district.

King Gorge sent a message of sympathy to the owners of the colliery.

NORWAY.

Advice has been received from the Sulitelma Company's mines in Norway, that for the month ending April 30th, 1910, 845 tons of concentrates containing 8.18 per cent. copper, were produced by the Elmore process.

GERMANY.

The Dynamite Company (formerly Alfred Nobel & Company), of Hamburg, states, in the report for 1909, that the less favourable situation of the coal and iron and steel industry exercised an influence upon the sales of explosives during the year, but the total turnover was very favourable as more satisfactory results were obtained in other branches of the company's activity. In order to enonomize freight charges and other expenses, a new factory has been erected at Saarbrucken for the manufacture of dynamite and other explosives, and it was recently set in operation. After appropriating £50,000 for depreciation in 1909, as compared with £34,500 in the preceding year, the accounts show net profits of £144,000, as against £106,000 in 1908, and it is proposed to pay a dividend of 22 per cent., as contrasted with 6½ per cent. in 1908.

TURKEY.

Interesting developments in connection with the petroleum deposits in Turkey are pending. The existence of considerable oil deposits in the vilayets of Morkul, Bagdad and Baskorak has been known for some time past, and it is now intended to commence exploitation in these districts. Refineries are to be built and liquid fuel to be introduced on the railways, in the fleet and in private industry. Rumours are in circulation that an American company has obtained an exclusive concession from the Government for the exploitation of these lands.

EGYPT.

Suez.—The third oil well at Jemsah has become a gusher. Dr. Ball and the staff of the Government Survey Department were present when the well was drilled in. One hundred and eighty tons of oil flowed in the first six hours. The flow was steadily increasing when it was shut off.

SOUTH AFRICA.

Johannesburg.—Mr. W. W. Mein, consulting engineer to Messrs. Ecksteins, is contributing a paper to the Association of Mining Engineers on Rand mine returns, criticizing as unscientific the much-discussed proposal by Mr. H. F. Marriott, consulting engineer to Messrs. Wernher Beit, to substitute per fathom for per ton in future statistics.

It has been decided to construct at once four seven-compartment shafts on the Modder State mines, two of which will be located at 2,000 feet on the line of contour and two at 3,000 feet. It is intended to dispense with temporary headgears with the view to economizing time and money.

AUSTRALIA.

The gold yield of New South Wales during the month of April was 15,381 ounces, valued at £52,149. The yield for the past four months was 75,301 ounces, valued at £269,544.

MEXICO.

Guadalajara, Mex., May 16th.—The Santa Domingo Mining Company, which is now controlled in Boston, has resumed development work in the Santo Domingo mines in the Hostotipaquillo district of this state. A party of twelve investors recently visited the mines, and two other parties will visit the properties during the next sixty days. The erection of a reduction plant is planned. But little work has been done in the Santo Domingo mines since the fall of 1908, but during the three years prior to that time several thousand feet of tunnels and drifts were driven. It is stated that since the resumption of development work high-grade ore has been opened in a new drift on the El Favor vein.

UNITED STATES.

Butte, Mont.—To some extent a curtailment policy was observed by the larger operating companies in Butte during the month of April and the total output, which amounted to 27,451,000 pounds of copper, was nearly 1,000,000 pounds less than for the month of March. The Butte-Ballaklava Copper Company has developed into a permanent producer and during April averaged about 72 tons of ore a day, the average mineral content being 10½ per cent., as no great quantity of second-class ore was shipped.

Butte, Mont.—During the month of April the Alex. Scott shaft was sunk to a total of 106 feet, making a record close to the highest record for deep-shaft sinking in the Butte camp. The shaft is now down about 1,524 feet and by June 1st it is anticipated that a depth of 1,600 feet will have been attained. At the latter depth a station will be cut and an electric pump will be installed. Also a crosscut will be run to intersect all of the veins traversing the property and the work of placing the mine in condition for heavy shipments will be pushed aggressively.

From the 500-foot level to the 1,400 the Alex. Scott has opened up a number of veins carrying copper and silver in commercial quantities. On the 1,400-foot level the main vein has been drifted upon to a considerable extent and an ore body more than 20 feet in width has been developed to the producing stage. The ore carries considerable bornite and copper glance, although in a conglomerate form, and it is believed that on the 1,600-foot level the ore will be found in a more compact form.

Goldfield, Nev., May 10.—The greatly extended scope of development at depth in the mines of the Goldfield Consolidated Company has rendered necessary the employment of a larger amount of electrical power and, to meet the growing requirements, the company is now preparing for the installation of a large storage battery and power equalizing plant at Jumbotown, a collection of houses a short distance from the town of Goldfield, situated near the Clermont and Laguna claims of the Consolidated.

Houghton, Mich.—The Michigan Copper Company in 1909 sold 1,979,305 pounds of copper at an average of 13.16 cents, yielding $260,551. By assessments its total income was swelled to $429,577. The annual report shows a deficit of $8,174, against $15,392 a year ago. President Brady considers the timber resources as of value, consisting of about 5,250,000 feet of excellent white pine, and an equal amount of hemlock and other timber. "A" shaft has been sunk to a depth of 2,133 feet and underground work tested values of the Minnesota vein, but nothing of interest was exposed. "B" shaft openings were confined to the 14th level east on the Calico lode.

There was opened from "C" shaft 894 feet on the Calico, 471 feet on the North Amygdaloid and 209 feet on the Minnesota vein. Light copper ground was shown on the 7th level west on the Calico. Both the 8th and 11th levels east were driven through excellent copper ground. The character of the copper contents at these points was spotty and its width averaged four to four and a half feet.

Deadwood, S.D.—E. C. Johnson, manager of the Gertie Tin Mining Company of Hill City, has recently received patents for a rock-grinding device which promises to have a marked effect on the ore-milling industry. In point of efficiency it is claimed to be far superior to any of the machinery now in use for the purpose and the demonstrations which have been made with models of smaller size than standard machine, appear to substantiate these claims.

The invention is called the Johnson Rod Tube Mill, its chief feature of difference from other tube mills in use being that instead of pebbles or chilled steel balls the grinding is effected by the use of chilled iron rods extending from end to end of the machine. The standard machine, as it will appear when turned out of the Homestake Company's shop, where it is now being put together, will consist of a metallic cylinder six feet in length by 18 inches in diameter. The inside surface is protected by a casting of corrugated chilled iron, against which the grinding is effected. The rods which extend practically the entire length of the mill, are sufficient in number to occupy one-quarter of the interior space of the cylinder. They are made of chilled iron with a core of rough iron.

Goldfield, Nev., May 16th.—The detailed statement issued by Manager J. R. Findlay, outlining the operations of the Consolidated Mines Company in April, shows that in point of production the record was surpassed in but one month of the company's history and exceeded the bullion output of March last, which heretofore has ranked second. This heavy production was made in the face of most unusual obstacles. On April 8th the mill was damaged by fire to the extent of $125,000, necessitating the complete closing down of the plant for a period of eight days, and resulting in a reduction of mill capacity since that time of 30 per cent. The great belt conveyor of 1,000 tons daily capacity, which carries the ore to the stamp bins, was destroyed, as were all stores of cyanide, zinc dust and materials employed in treatment, together with thirty of the stamps.

Victor, Colo.—Stratton's Independence, Limited, operating at Victor, Colo., paid on April 29th last a dividend of $60,000, bringing up the dividends paid during the first nine months of the fiscal year to 15 per cent. per annum on the capitalization of the company.

The cyanide mill is in steady operation, treating by cyanidation and concentration nearly 7,000 tons a month of low-grade dump ore, while the mine is producing better than 2,000 tons a month or one and one-quarter ounces ore.

The combined earnings of mine and mill, as published in London, amounts to 20 per cent. per annum on the capital.

Coalinga, Cal., May 16th.—In another two weeks the Producers Transportation Company's pipe line system, tapping the five big oil fields of the San Joaquin Valley, will be in complete operation, and crude oil from Coalinga, mingling with that from Kern River, McKittrick, Sunset and Midway, will start from the Junction on its journey to the sea, and hence into the markets of the world.

Globe, Ariz.—As a conservative estimate, the first of January, 1911, is set as the date for the beginning of production of ore from the mine of the Miami Copper Company. The concensus of opinion among the members of the management is that within six months from date, or by the first part of November, the concentrating plant, including the power plant and water system, will be completely equipped for handling a daily ore production of 1,000 tons, which output will be increased shortly

afterward to 2,000 tons, the tonnage for which the plant was originally designed. Although the construction plans have been changed and a concrete foundation built for a mill of a capacity of 3,000 tons daily, the third unit will not be added until a later date. At present, most of the concrete work is completed, and the steel frame for the concentrator building is well advanced, so that the principal construction work in the future will be that of installing the various machines in the concentrator and power plant buildings. Large shipments of machinery and structural steel are received almost daily, and with a force of nearly 500 workmen, a large number of whom are skilled machinists, these shipments will be readily taken care of.

Washington, D.C., May 17th.—President Taft has signed the bill creating a bureau of mines, but has as yet taken no action looking to the appointment of a chief of the new branch.

The bureau was created for the purpose of making diligent investigation of the methods of mining, especially in relation to the safety of miners, and the appliances best adapted to prevent accidents, the possible improvement of conditions under which mining operations are carried on, the treatment of ores, and other mineral substances, the use of explosives and electricity; and other inquiries and technological investigations pertaining to the mining industry.

The new bureau will be a branch of the Interior Department. Work in connection with mining which is now being conducted by the Geological Survey, a bureau of the Interior Department, will be transferred to the mines bureau. Such work includes the investigation of structural matters, the analyzing and testing of coals and the ascertaining of the causes of mine explosions.

While the act creating the new bureau was designed largely to practicalize the investigations of the Geological Survey and meet the demand for action to prevent the constantly recurring coal mine explosions throughout the country, it was drawn on broad enough lines to permit of the extension of many benefits to mines where explosions do not often occur.

The bureau of mines is to be under control of a director who will receive a salary of $6,000 a year. J. F. Callbreath, of Denver, secretary of the Mining Congress, has joined in a petition to the president for the appointment of Dr. J. A. Holmes, of the Geological Survey, to the position.

ALASKA.

Valdez, May 14th.—The first attempt at quartz mining in this district has proved highly successful, returns received here to-day from the first eighteen days' operations of the Cliff Mining Company's claim showing an output of 860 ounces of gold, besides $4,000 in concentrates, from 150 tons of ore.

The company was organized eight months ago to develop the quartz vein on Valdez Bay, and a thousand foot tunnel and an uprise was driven, and a three-stamp mill installed.

COMPANY NOTES.

INTERNATIONAL COAL.

The annual report of the International Coal & Coke Company, which has just been issued, shows that the net profits for the year, after paying all operating expenses at the head office and the mine, amount to $246,271, which sum has been derived from the various departments of the company's coal and coke business.

Four quarterly dividends at the rate of one and a quarter per cent., amounting to $145,000, were paid, the balance, $101,271, being carried to the surplus account, which now reaches the handsome sum of $34,595.

The president's report says that during the year development work proceeded apace, some 2,303,352 tons being in sight on December 1st, 1909, after due allowance for working and waste had been made. These figures show a net gain of 323,352 tons developed over and above the tonnage extracted.

The Hedley Gold Mining Company, which purchased the famous Nickel Plate mine and reduction works at Hedley last August, has issued a statement covering its operations during 1909.

The company took an option on the property in May of last year for $715,000, which was exercised on August 13th, 1909. During the life of the option exploratory work was carried on and the new company received half of the profits made during that period, its share amounting to $15,748.89. The net profits from August 13th to December 31st were $68,812.57. The first dividend of three per cent. was paid January 4th, 1910, leaving a surplus as of December 31st, 1909, of $79,041.46.

Mr. I. L. Merrill, president of the Hedley Gold Mining Company, in his report to stockholders last month, says: "At present we are wholly dependent on our water power. Low temperatures and drought interfere with this power and stop our mill. We have been fairly fortunate this winter, losing but little time until February 24th, when a temperature of 24 degrees below zero shut down the mill. We hope to be able to resume by or before April 1st. Our engineers are figuring on building a larger dam, to give a water power that would be unaffected by weather conditions; or, as an alternative, adding an auxiliary steam plant to run the mill when our water power fails.

"Prior to our taking possession of the property the tailings were wasted. We are now impounding them and a substantial profit is hoped for from their retreatment. Your president, with the aid of the best experts, is conducting experiments to determine character of needed changes in reduction plant. The changes can probably be made this summer. They should increase the tonnage of ore handled and save most of the gold now going into the tailings. The additional recovery hoped for is estimated at $1.25 per ton of ore treated.

"Your president believes that the outlay needed to enlarge and improve the reduction plant and power plant will not exceed $100,000. The company at its inception, was provided with $280,000 working capital, so that the cost of new plant is much more than provided for. No outlay will be made until we are satisfied that it will be quickly repaid by increased profits."

The production returns from August 12th to December 31st, 1909, were as follows:

	Tons Milled.	Assay Value.	Net Profits.
August and September...	6,092	$11.90	$18,190.70
October	3,914	11.75	16,186.68
December	3,392	12.80	14,556.29
November	3,691	12.76	17,918.01

The company has since declared its second quarterly dividend of three per cent., which was payable on April 2nd last.

The Temiskaming Mining Company has issued a statement for the first three months of the fiscal year. Profits for the quarter ending April 30th were $96,684.05, which practically places the company out of debt. The statement of the president claims the mine is now working in good ore, and that excellent results are being obtained from the concentrating plant, although the work at the mill was retarded owing to the delay in getting sufficient electric power.

STATISTICS AND RETURNS

Cobalt, Ont., May 10th.—For the first four months of 1910, the following ore shipments were made from the Cobalt district:

	Tons.
Nipissing	1,958.81
La Rose	2,082.81
Kerr Lake	1,446.00
Crown Reserve	962.21
McKinley-Darragh	483.05
Buffalo	356.14
Drummond	332.10
Right of Way	305.05
Coniagas	257.48
O'Brien	244.67
Temiskaming	208.25
City of Cobalt	142.83
Trethewey	186.73
Cobalt Central	127.74
Chambers-Ferland	112.68
Cobalt Lake	97.30
King Edward	87.98
Peterson Lake	85.22
Colonial	62.68
Hudson Bay	61.68
Silver Cliff	33.00
Waldman	32.00
Cobalt Townsite	27.25
Hargraves	20.90
Casey Cobalt	10.00
Total	9,724.24

Gowganda and Elk Lake shipments, bringing the total for the northern Ontario camps up to 10,065 tons. Bullion shipments to the amount of $96,750 have been made.

This compares favourably with 9,456.68 tons for the first four months of 1909, and 5,650.01 for 1908.

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending May 20th, and those from January 1st to date:

	May 20. Ore in lbs.	Since Jan. 1. Ore in lbs.
Beaver		120,450
Buffalo	66,000	825,558
City of Cobalt		363,835
Chambers-Ferland	64,260	291,060
Cobalt Central	46,300	293,265
Cobalt Lake		196,000
Cobalt Townsite		68,000
Colonial		107,260
Coniagas	52,400	623,795
Crown Reserve	84,000	2,381,295
Corkill E. P.		65,000
Drummond		664,200
Hargraves		41,800
Hudson Bay		123,695
Kerr Lake		3,077,991
King Edward		174,966
La Rose		4,824,003
McKinley	201,408	1,246,579
Nipissing	120,400	4,372,541
O'Brien	64,100	648,046
Peterson Lake		270,450
Right of Way		616,757
Silver Cliff	51,500	117,510
Temiskaming		421,830
Trethewey	63,700	447,650
Waldman		63,992

Ore shipments for the week ending May 13th were 814,068 pounds, or 407 tons.

Total shipments from January 1st to May 13th were 22,447,580 pounds or 11,223 tons.

CONSOLIDATED MINING AND SMELTING COMPANY'S RETURNS.

Following are the production returns of the Consolidated Mining & Smelting Company of Canada for the month of March last and the eight months previous:

Metals Produced in March.

	Quantity.	Value.
Gold	12,487 oz.	$254,507
Silver	178,542 oz.	92,368
Copper	468,565 lb.	62,267
Lead	3,766,388 lb.	106,565
Total value		$515,798

Production During Nine Months, to March 31st.

Gold	101,340 oz.	$2,074,853
Silver	1,548,780 oz.	808,013
Copper	4,500,754 lb.	590,197
Lead	31,851,801 lb.	896,357
Total value		$4,367,420

Percentage of Value of Production.

	March. Per cent.	Nine Months to Mar. 31. Per cent.
Gold	49.34	47.51
Silver	17.91	18.45
Copper	12.07	13.51
Lead	20.68	20.53

For purposes of comparison the following figures, being the company's production at its smeltery at Trail, for the fiscal year ended June 30th, 1909, are here given: Gold, 114,920 oz.; silver, 2,443,475 oz.; copper, 4,637,631 lbs.; total value, $5,505,526. It should be noted that these figures are for twelve months while those given in the second table above are for only nine months.

B. C. ORE SHIPMENTS.

(Week ending May 14th.)

	Week.	Year.
Boundary.		
Granby	22,509	473,130
Snowshoe	22,483	69,273
Other Mines		146,098
Total	24,992	688,501
Rossland.		
Centre Star	3,849	73,818
Le Roi No. 2	621	11,665
Le Roi (milled)	300	5,700
Le Roi	275	5,400
I-X-L	007	041
Other Mines		229
Total	5,052	96,857
Slocan-Kootenay.		
St. Eugene (milled)	2,775	52,725
Whitewater (milled)	600	11,400
Van Roi (milled)	800	15,200
Kootenay Bell (milled)	70	1,330
Granite-Poorman (milled)	250	4,750
Queen (milled)	420	7,980
Nugget (milled)	110	2,090
Van Roi	122	511
St. Eugene	368	7,024
Rambler-Cariboo	021	378
Sullivan	129	4,033

Richmond Eureka	29	1,719
Ferguson	60	385
Yankee Girl	128	2,392
Other Mines		21,845
Total	5,882	133,762

Total shipments for week, 35,926 tons, and for year to date, 919,120 tons.

Smelter Receipts.

	Week.	Year.
Granby, Grand Forks	22,509	473,250
Consolidated Co., Trail	8,323	188,210
B. C. Copper Co., Greenwood.		145,935
Total tons	30,832	807,395

TORONTO MARKETS.

Metals.

May 23.—(Quotations from Canada Metal Co., Toronto.)

Spelter, 5½ cents per lb.
Lead, 3.65 cents per lb.
Antimony, 8 to 8½ cents per lb.
Tin, 34.50 cents per lb.
Copper, casting, 13.75 cents per lb.
Electrolytic, 13.75 cents per lb.
Ingot brass, 9 to 12½ cents per lb.

May 23.—Pig Iron (Quotations from Drummond McCall Co., Toronto.)

Summerlee No. 1, $23.50 to $24.00 (f.o.b. Toronto).
Summerlee No. 2, $23.00 (f.o.b. Toronto).
Midland, No. 1, off the market.
Hamilton, No. 1, $21.00 (f.o.b. Hamilton).
Hamilton No. 2, $20.50 (f.o.b. Hamilton).
Clark's, $21.00 (f.o.b. Toronto).
Cleveland, $20.50 (f.o.b. Toronto).
Coal, anthracite, $5.50 to $6.75.
Coal, bituminous, $3.50 to $4.50, for 1¼-inch lump.

Coke.

May 20.—Connellsville coke (f.o.b. ovens).

Furnace coke, prompt, $1.70 per ton.
Foundry coke, prompt, $2.25 to $2.35 per ton.

May 20.—Tin (Straits), 33.35 cents.

Copper, Prime Lake, 13.00 cents.
Electrolytic copper, 12.75 to 12.85 cents.
Copper wire, 14.25 cents.
Lead, 4.40 to 4.50 cents.
Spelter, 5.35 to 5.40 cents.
Sheet zinc, (f.o.b. smelter), 7.50 cents.
Antimony, Cookson's, 8.37½ cents.
Aluminium, 23.25 to 24.00 cents.
Nickel, 40.00 to 49.00 cents.
Platinum, ordinary, $29.00 to $29.50 per ounce.
Platinum, hard, $34.50 per ounce.
Bismuth, $1.75 per lb.
Quicksilver, $48.00 per 75-lb. flask.

SILVER PRICES.

NOTICE

STUDENTS EMPLOYMENT REGISTER,

The CANADIAN MINING JOURNAL has opened an employment register for students taking mining or metallurgical courses at Canadian Universities or Technical Colleges. Mine operators who wish to employ students during the summer months are requested to communicate with the Business Manager.

Students are requested to send in their names, along with brief records of experience. These will be filed and no effort will be spared on our part to place applicants in immediate communication with possible employers.

Save 50% of the Power
by using NISSEN STAMPS

Descriptive Pamphlets on request

Owing to the great crushing efficiency secured the power required to operate Nissen Stamp Mills is about half that of other mills of the same capacity output.

One user writes :—

THE CANADIAN FAIRBANKS CO., TORONTO, ONT.

Dear Sirs,

In answer to your inquiry regarding the Nissen Stamps supplied by your firm. These stamps are running steadily on some of the hardest rock on the Continent, they are crushing 5.3 tons of ore per head in twenty-four hours. The feed rolled down to go through about a one inch hole.

The screen used for the above tonnage was 30 x 30 mesh, 28 gauge wire, opening .018. With a coarser screen the tonnage would of course be larger.

The shoes and dies wear even, and the splash is well distributed over the screen.

The arrangements for keeping up the weight of the stamps are very good.

I can recommend the Stamps. Yours truly,

(Sgd.) F. J. Bourne, Superintendent,

Canadian Mining Journal - Toronto

This year we are building **Green Silk Tents** which we believe will be popular with Tent users. They are no heavier in weight but have an advantage over white color, for **sleeping purposes** so that one is not awakened by the early rising sun, and can sleep in comfort. All sizes at reasonable prices.

We are sole manufacturers of STANDARD WEATHERPROOF DUCK TENTS, Tarpaulins, etc. For Camp Beds, Chairs, Stoves, Grey Blankets or any other supplies. Send your orders to

Agents Everywhere PETERBOROUGH, ONT.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

GEOLOGICAL SURVEY

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, and with many local areas and special subjects.

MARITIME PROVINCES

The whole of Cape Breton, and a large portion of the coal and gold fields of Nova Scotia, have been reported upon, and mapped on a scale of 1 mile to 1 inch. The remaining portions of the Province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter Provinces, mapped on a scale of 4 miles to 1 inch.

QUEBEC

Quebec, south of the St. Lawrence, has been reported upon, and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the Province north of the St. Lawrence are also available.

ONTARIO

A large part of the Province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

THE PRAIRIE PROVINCES

Geological maps and reports have been issued covering the greater part of the Provinces of Manitoba, Saskatchewan, and Alberta.

BRITISH COLUMBIA

The southern portions of British Columbia, as well as other parts of the Province, have been reported upon and mapped.

YUKON

Many of the important areas in the Yukon have been reported upon and mapped.

THE NORTH WEST TERRITORIES

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of a report or map will be sent to Canadian applicants free of cost, and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

Applications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.

THE FOLLOWING GEOLOGICAL MAPS HAVE RECENTLY BEEN ISSUED:

CANADA

1084. General Geological Map of Canada. Scale 100 miles to 1 inch.

NOVA SCOTIA

1019. City of Halifax Sheet.
1025. Waverley Sheet.
1037. Windsor Sheet.

The above sheets belong to the regular series of Nova Scotia map sheets on a scale of 1 mile to 1 inch. The first includes Halifax City and Harbour, the second the Waverley Gold District, and the third Gypsum Quarries.

ONTARIO

1023. Geological Map showing position of Corundum-bearing rocks in Central Ontario.
1076. Gowganda Mining Division.

This map besides representing the geology of the Gowganda area, represents the geography of a considerable area to the east and north.

980. Portion of Algoma and Thunder Bay districts, Ontario, 1908. W. J. Wilson.
1081. Region lying north of Lake Superior between the Pic and Nepigon Rivers, Ontario, 1906. W. H. Collins.

BRITISH COLUMBIA

1002. Geological Sheet, Special Map of Rossland.

This map, on a scale of 400 feet to 1 inch, besides accurately indicating the topographical and cultural features, shows the geology and location of veins.

1004. Geological Sheet, Rossland Mining Camp. Scale 1200 feet to 1 inch.
1074. Sketch map of Sheep Creek Mining Camp, West Kootenay, B.C., scale 1 mile to 1 inch.

YUKON

1041. Geological and Topographical Map of Whitehorse Copper Belt. Scale 1 mile to 1 inch. Also several detail maps of same belt.

NOTE.—Maps recently published may be had on linen cloth, for use in the field, at 10c. per copy.

REPORTS

1072. Summary Report of the operations of the Geological Survey for year 1908.
1085. Descriptive Sketch of the Geology, and Economic Minerals of Canada. G. A. Young. Introduction, R. W. Brock.
1075. Gowganda Mining Division, 1908. W. H. Collins.
1035. Coal Fields of Manitoba, Saskatchewan, Alberta, and Eastern British Columbia, 1908. D. B. Dowling.
1050. Whitehorse Copper Belt, Yukon. R. G. McConnell.

NEW CATALOGUE

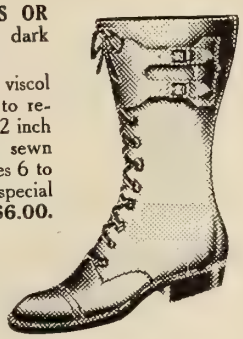
1073. Catalogue of Publication 1843—1909.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

THE CALL OF THE WILD

The Opening Season is calling hundreds of enthusiastic prospectors away to their summer's labor in the wilds.



If you are Going, What About Requirements?

In many lines we are peculiarly fitted to help you get your outfit. From watches, instruments and firearms to tents, flybars and clothing we handle most of the necessaries.

OUR SPECIAL BOOT FOR MINERS OR PROSPECTORS is made from heavy, dark "tan colored" winter calf.

The leather is treated in a solution of viscol oil, makes them soft and pliable, helps to resist the wet. It's high cut, having a 12 inch left with heavy double goodyear welted sewn soles and bellows tongue to top. Sizes 6 to 11. The highest kind of value at the special price per pair.....**$6.00.**

NOTE:—We recommend the use of "Visole" to be applied freely which will give additional wear to the leather, per tin 15c.

Compound arnica and witch hazel. This is the best preparation we know of for putting on bruises, if applied immediately it saves the hurt one much suffering, it soothes the pain and reduces the swelling, the bruise not getting black at all. Price pint bottle 50c. quart bottle $1.00, small bottles 15 and 25c.

Mosquito and black fly oil applied over the exposed parts, will prevent insects from biting, 4 oz. bottle 25c., per gallon $7.25.

Peruvian Ointment, an antiseptic healing ointment for burns, scalds, cuts, sores, etc. Price per bottle 15c. per lb., jar 75c.

Bandages (cotton) all 6 yard lengths.
1 inch wide.....2 for 5 per doz. .30
2 " " .....5 each, 6 for .25
2½ " " .....5 each, per dox. .60
3 " " .....2 for .15, 4 for .25

Zinc Oxide Adhesive Plaster on spools, 5 yard lengths. For strapping up cuts, broken ribs, or any purpose where strapping is necessary. ½ inch wide 30c. each; 1 inch wide 40c. each; 2 inches wide 60c. each.

New Skin, an antiseptic waterproof liquid court plaster, for cuts, burns, blisters, etc., Price 15c.

Fine cold drawn castor oil, pint bottle 20c.

Lewis Astringent cordial for diarrhoea, cramps, etc., 4 oz. bottle 25c.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are: Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows:

All mines belong to the Goverment of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unserveyed territory, is open to prospecting.

Miners' Certificates good for a calendar year may be obtained by sending $10.00 to the Department of Mines. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minium being 40 acres in unserveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of $10.00 plus a yearly rental of $1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed territory may be purchased as a mining concession at the price of $20.00 per acre if within 20 miles of a railway in a straight line, or $10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

The Hon. Minister of Colonization, Mines and Fisheries
Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

NOBEL GELIGNITE

It always breaks cleanly to the bottom of the drill holes and is free from fumes of any kind. Equal to 75% Dynamite and is sold at a price producing very much better results in terms of Rock Broken or Extracted and money spent.

"WINTER BRAND" DYNAMITE

Is only one strength, if anything, a little stronger than 50% Dynamite. **It does not freeze,** or rather, explodes with perfect efficiency when frozen **and needs no thawing.**

"AUTUMN BRAND" DYNAMITE

Is packed in all the usual percentages. The powder is similar in appearance, character and effect to ordinary Dynamite, except that the freezing temperature of the Nitro-Glycerine is reduced from 42° F to a little under 30° F.

PERMITTED EXPLOSIVES for Coal Mines

Nobel Monobel, Saxonite and Carbonite.

Air Valves of Hoerbiger patent type; very reliable and noiseless in working

Copy of letter from The Eldorado Banket Gold Mining Co., Ltd., Eldorado Mine, Rhodesia, to Messrs. Reunert & Lenz, Salisbury.

Dear Sirs:—

I have much pleasure in testifying to the good work done by the 10 drill Belliss Morcom Air Compressor supplied by you to this Company. It started work in May of last year, and since that time it has had hardly one minute stoppage.

At present the Compressor drives 7 large Ingersoll Sergeant Drills, 2 large Air Hoists, and 3 underground Pumps,

Yours faithfully,
(Sgd) H. STEPHAN,
Manager.

"CLEVELAND" STOPE DRILLS

EFFICIENCY:—Of course you want the stope drill which has the highest efficiency, but you must pick out the one that will have as high an efficiency a year from to-day. Isn't it true that your stope drills decrease steadily in efficiency as they grow older?

REPAIRS:—Repairs which must be made from time to time after the part has given long and satisfactory service, are not a source of dissatisfaction, but dont you find that your stope drills are constantly needing something new?

DRILLING CAPACITY:—As long as your stope drill will put in sufficient holes per shift to drill up your stope there is no argument in favor of your changing to our drill just becanse it will drill faster. We know that. But we know that the "CLEVELAND" Stope Drill will do as much work per shift when it is one year old as it will when one week old, and that is what you want, isn't it?

THE "CLEVELAND" Whether you purchase your stope drills after considering efficiency, repair cost, or drilling capacity, the "Cleveland" should be the stope drill you specify, for its design is such that the initial efficiency is the highest possible in an air tool, and the piston and valve action are so related that the "Cleveland" is just as efficient when it is a year old as when it is brand new; we **know**, and our information is gained from hundreds of installations that the "CLEVELAND" will cost less for repairs **per year** than any stope drill made; a 30 day trial will convince you that the "CLEVELAND" will drill as much per shift as any other stope drill, and we have machines always in stock ready to ship for trial if you will drop us a line, As you have everything to gain and nothing to lose, why not investigate NOW?

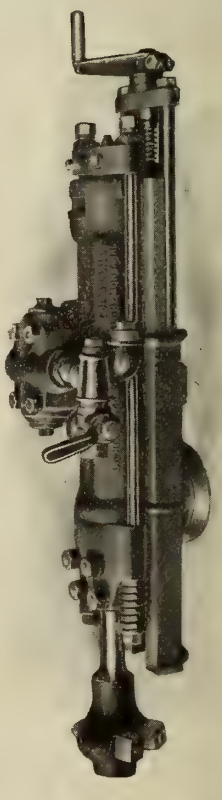
CHOOSE THE RIGHT DRILL
FOR YOUR PARTICULAR CONDITIONS.



If too small, your drill holes will not be large enough or deep enough to shoot the rock economically; or your repairs will be unduly high.

If too large, labor and power will be excessive. Some valve-motions work well on heavy pressure, against hard even rock, others excel in soft or broken ground, on lower air pressure.

There is a Sullivan Drill which may be relied on to develop the highest possible efficiency and economy under any given set of working conditions.

As specialists in fitting drills to the service required, we solicit your inquiries.

Amatite ROOFING

NEEDS NO PAINTING

MOST ready roofings require special painting and coating, and unless this is done regularly, you are sure to have leaks and trouble right along.

If you use Amatite, nothing of the sort is required. You will have real roof protection *without painting* of any kind.

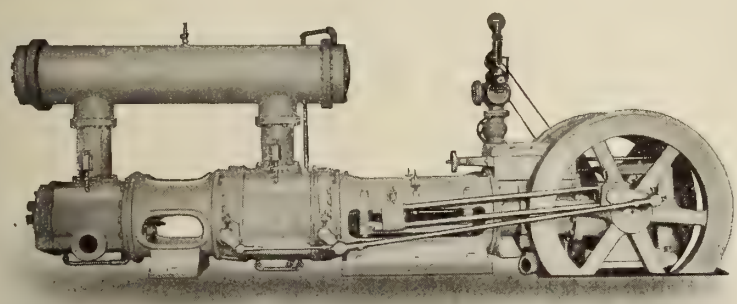
Amatite is made to stay waterproof and give protection year after year, without any thought or care on your part.

First—Because it is waterproofed with Coal Tar Pitch.

Second—Because it has a real Mineral Surface.

Amatite, owing to these features, is the most economical roofing made. Its first cost is low, and you are *saved* all future expense for repairs or paint because it will need neither.

If you haven't seen Amatite, write for a sample to-day. From it you will very quickly understand why it doesn't require painting; why it does not leak; and why it saves you money.



Address nearest office to-day.

Another Victory for the "DEISTER"

We are placing 180 Improved No. 3 Deister Slime Tables and 132 No. 2 Deister Sand Tables in the Miami Copper Company's mill, Miami, Arizona. This large order was the direct result of the showing made by the Deister Tables. The No. 2 Deister competing against all of the well-known makes of tables on the market—The Improved No. 3 Deister competing against vanners.

By eliminating teeth in the roller and rocker arm, our driving mechanism is now the most effective, noiseless and durable on the market.

The Davis Handbook

OF THE

Cobalt Silver District

By H. P DAVIS.

ILLUSTRATED WITH PHOTOGRAPHS

¶ The first section of this volume is an outline on the Geology, Mining Treatment and Marketing of the Ores of the Cobalt District, the object being to give all the data and general information necessary to guide investors, brokers and professional men generally.

¶ Included in this volume is a complete and accurate directory of all mining companies operating or organized to operate in the Cobalt Silver District of Ontario.

¶ Full information as to capitalization, directorates, locations and conditions of properties is given. Tabulated statements of production and dividends revised up to January, 1910, are included.

PRICE $1.50 PAPER COVER $2.00 STIFF COVER

BOOK DEPARTMENT

Canadian Mining Journal

TORONTO

A New, Complete and Authoritative Treatise.

Cyanide Handbook

By J. E. CLENNELL.

Over 500 pages, 6x9, illustrated, $5.00 (21s) net, postpaid.

Mr. Clennell has been in close touch with the rapid developments of cyaniding. He has been instrumental, too, in many important discoveries, and his work in this field has taken him to the leading plants of the world. It deals generally with Cyanide and does not confine itself to the process alone. It is divided into nine main parts covering the subject more fully and exactly than it has heretofore been handled.

Especially noteworthy is the full treatment of recent developments and important phases heretofore *inadequately treated.*

CONTENTS

Part I. General.

Introduction.—I. Early History of the Cyanide Process. II. Outline of Operations in the Cyanide Process.

Part II. Chemistry.

I. Cyanogen and its Compounds with Non-metals. II. Simple Metallic Cyanides. III. Metallic Compounds of Complex Cyanogen Radicals. IV. Chemistry of the Dissolving Process. V. Chemistry of the Precipitation and Smelting Processes. VI. Manufacture of Cyanide.

Part III. Preparatory Treatment of Ore for Cyaniding.

I. Crushing Machinery. II. Grinding Machinery. III. Mechanical Handling of Material for Cyanide Treatment. IV. Hydraulic Classification, Separation and Settlement of Slimes. V. Amalgamation and Concentration.

Part IV. The Dissolving Process.

I. Percolation. II. Agitation. III. Filtration by Pressure and Suction. IV. Handling of Solutions.

Part V. The Precipitation and Smelting Process.

I. Zinc-Box Construction and Practice. II. Clean up of Zinc-Boxes. III. Acid Treatment and Roasting of Precipitate. IV. Fluxing, Smelting and Refining of the Precipitate.

Part VI. Special Modification of the Cyanide Process.

I. Direct Treatment after Dry or Wet Crushing. II. Crushing with Cyanide Solution. III. Roasting before Cyanide Treatment. IV. Use of Auxiliary Dissolving Agents. V. Electrolytic Precipitation Process. VI. Other Precipitation Processes. VII. Treatment of Cupriferous Ores.

Part VII. Assaying.

I. Sampling. II. Assay of a Typical Siliceous Ore. III. Roasting III. Special Methods of Assay for Particular Ores and Products. IV. Assay of Gold and Silver Bullion.

Part VII. Analytical Operations.

I. Analysis of Ores and Similar Siliceous Material. II. Analysis of Bullion and other Mainly Metallic Products. III. Analysis of Cyanide Solutions after Use in Ore Treatment. IV. Analysis of Commercial Cyanide. V. Analysis of Sundry Materials.

Part IX. Metallurgical Tests.

I. Density Determinations. II. Alkali Consumption Tests. III. Screening and Hydraulic Separation. IV. Concentration and Amalgamation Tests. V. Cyanide Extraction and Consumption Tests. VI. Useful Formulae.

CLUBS, SOCIETIES, AND AN EDITOR.

Again has our young contemporary, "The Mining Magazine," opened a vexed question. In its issue for May, Mr. F. Lynwood Garrison takes the editor, Mr. T. A. Rickard, to task for making caustic remarks about the Mining and Metallurgical Society of America, which society is a close corporation, composed exclusively of professional men. Mr. Garrison, not without heat, advances the argument that since the Society was organized to promote reforms advocated editorially by Mr. Rickard, therefore Mr. Rickard, who is a prominent member of the Society himself, is unfair and inconsistent in commenting adversely upon such an "altruistic organization." "Moreover," says Mr. Garrison, "you would not venture to do such a thing of [sic] any social club in which you are a member, and it is hard to see much difference in propriety as regards the Mining and Metallurgical Society."

To these strictures Mr. Rickard replies in an editorial. First he points out that there is a great gulf fixed between a social club and an engineering association. The Mining and Metallurgical Society he had criticized because it adopted the exclusiveness of a social club. For the one, "carefully prescribed qualifications as to occupation, experience, and skill" are the essentials. For the other it is merely necessary that the candidate be "congenial to those already in the club." Mr. Rickard further sums up his position thus: "Any society arrogating national or international scope, any society claiming to include all the properly qualified practitioners, any society assuming the function of professional classification, is in the position of . . . a public functionary bound to act in accordance with prescribed rules, not a private person free to give vent to his own idiosyncrasies."

To this well expressed dictum we subscribe. The whole discussion has arisen because of several misconceptions. The Mining and Metallurgical Society of America was created to perform a function that could not be performed by that excellent institution, the American Institute of Mining Engineers. Like our own Canadian Mining Institute, the American Institute exists to represent primarily the industry of mining. Our own choice of name has been more fortunate. But in all important respects the two bodies are analogous. Both are heterogeneous aggregations of persons directly and indirecly interested in mining. The Canadian body is probably the more effective, as it concerns itself in legislation. But each is controlled by professional men of the highest rank. Both have rejected definitely any proposals tending towards exclusiveness. The usefulness of each is believed to depend upon well regulated inclusiveness.

On the other hand, the Mining and Metallurgical Society purports to represent the profession. This it cannot do so long as admission to membership is denied to any man whose qualifications meet the Society's requirements. Like a University, it can deny its degree to no fit person.

In one direction in particular, the Mining and Metallurgical Society appears to have got on the wrong trail. Members, we believe, are not permitted to advertise the fact that they are members. This defeats the very purpose of the organization and removes the only effective means of discipline. The organizers overlooked the patent fact that, as the engineer looks to the public for his living, so his standing is dependent upon what the public thinks of him. In other words, the Society must not become a Star Chamber. It should and must strive not only to regulate the profession, but to secure the sympathy and assistance of the nation.

One word in closing. Mr. Garrison in his letter refers to the Society as being an altruistic organization. This is piffling. No professional body is altruistic . Altruism is a colourless something that can perhaps be postulated of religious retreats. The Mining and Metallurgical Society is a body organized to protect the profession of mining engineering. Its prime object, therefore, is self-preservation. Its chief danger is priggery.

QUEBEC MINING LAW AMENDMENTS.

A new spirit has been infused into the administration of mining affairs in the Province of Quebec. Close on the heels of the departure of the Chibougamau Commission comes the announcement that certain changes have been made in the mining laws. The object of these changes is to make the way easy for the prospector and the miner. The mining laws of Quebec have long needed attention. They are now being altered and amended so as to render them a help and not a hindrance to the pioneer and investor. In this respect Ontario, burdened with equivocal, cumbrous, and most involved legislation, falls far behind Quebec. Comparisons may be odious, but they have too often been made at Quebec's expense.

The amendments referred to are six in number. We shall glance at them one by one.

By the new provisions all building materials, clays, limestone, peat, ochres, sands, etc., found on private lands belong to the owner of the surface rights. Under the old regulations, the mining rights for these substances had to be acquired from the Crown. This amendment inures to the benefit of the farmer, if to anyone at all.

In future all sums paid on mining licenses (which are practically yearly leases of mining rights) shall be deducted from the price when mining claims are acquired from the Crown by purchase. This is distinctly beneficial to the mining man.

Formerly a period of four months was allowed between the staking out of a claim and the taking out of the mining license or the consummation of the purchase. By the late amendments this period is now extended to six months.

Penalties for tampering with stakes was punishable by a fine of $25, or one month imprisonment. The fine is now placed at $200, and the alternative imprisonment at six months.

Under the old regulations the deposits of iron sands in the lower St. Lawrence region were purchasable at the rate of $10 per acre. The Lieutenant-Governor-in-Council is now authorized to reduce this price to four dollars per acre should he deem it advisable.

The last point of change is one relating to municipal taxation of mines and mining plants. In the year 1900, a law was passed exempting all mines and mining plants from municipal taxation for a period of ten years. This measure expires in July of this year. It is now replaced by an amendment exempting the mine itself and the underground plant, but providing that the surface plants, mills, buildings, etc., are taxable by the municipalities.

We believe that there is little to find fault with in these amendments. But there is much to commend in the obvious intention of the Quebec authorities.

PROGRESS AND PROCRASTINATION.

On another page will be found notice of the programme of the Federal Mines Branch for the coming season. We are pleased to find that a British expert has been invited to visit Canada and consult with the Government with regard to the regulation of the manufacture and storage of explosives. No delay should occur in taking up this most necessary investigation.

Other timely investigations are to be undertaken. Amongst these are such questions as the utilization of peat, the treatment of iron pyrite, the production of spelter and zinc oxide, the magnetic concentration of iron ores, etc., etc.

These activities will bring results. It is regrettable, however, that one most urgent problem has been overlooked. In an editorial in our last issue we pointed out that the Hon. Mr. Templeman promised last session to give attention to the matter of life salvage in coal mines. On the programme just issued we see no reference to this. Again it is necessary to exhume the humiliating fact that an officer of the United States Geological Survey had to be called in to instruct the miners of Nanaimo in the use of breathing apparatus. By all means let somebody move.

For the information of all interested, we publish on another page a review of the action taken by other governments.

THAT TIMMINS SAMPLE CAR.

One thing that has contributed to what may be a much exaggerated rating of Porcupine is the Timmins sample incident. In a recent editorial we referred briefly to this. Since writing that editorial we have received what appears to be more authentic information. Some of this we are not at liberty to use. But we are quite free to

refer to the fact that serious doubts have been expressed by several engineers as to the representative character of the Timmins sample.

Now, whatever the actual facts may be, the Messrs. Timmins are in nowise bound to make public the history of that sample unless it is their intention to interest the public in their enterprise. In this event they have no right to expect the public to consider their statements unless those statements are backed by a full technical record of the sample.

On the other hand, if the Messrs. Timmins intend to develop their property without selling shares to the public, they have every right to suppress particulars. But, until those particulars are published, all that can be accepted is that a car-load of rich ore has been mined in Porcupine.

. . . . . .

No good object can be served by shutting our eyes to facts. Porcupine is decidedly *not* a proved district. Development has been and will be slow. The prices asked for undeveloped prospects are preposterous. Frequently the elements of a decent gamble are lacking. As against these facts, however, it must be remembered that rich ore has been found on several claims. How extensive the enrichment is in each case is known by no one. Only careful, competent engineering can determine this.

Owners of claims, anxious to sell quickly and at the top of the market, may resent plain speech. But exaggeration is precisely what has before now killed gold mining in Ontario. The CANADIAN MINING JOURNAL will rejoice exceedingly if Porcupine becomes a successful mining region. But whatever grounds we may have for *hope*, we have not yet a sufficient basis for *belief*.

THE HAIR-TRIGGER CRITIC.

Having passed through Egypt on his way to the "desired metropolis," Mr. T. Roosevelt finds himself impelled to inform the British nation that it is not doing its full duty by that country of historic trouble. As a critic, Mr. Roosevelt falls into the hair-trigger class. Sub-conscious cerebration provided him with his criticisms long before he saw Egypt. Egypt furnished local colour. The fact is that it is Great Britain's misfortune not to have conformed to Mr. Roosevelt's own methods.

Mining centres ever and anon are touched up by the same species of critic. The hair-trigger critic is often desperately in earnest and unquestionably honest. But either he is incapable of seeing beneath the surface, or else he is temperamentally incapable of taking sufficient pains to inform himself on both sides of his subject. The worst of him is that he may frequently become the innocent mouthpiece of extreme partisans.

PORCUPINE.

Porcupine is so much discussed at present that we feel no compunction in assigning it a large amount of space. We would request our readers to ponder carefully the articles contributed by Mr. Haultain. They are characteristically vigorous and timely. Dwellers in Porcupine will do well to take them to heart.

The general article by Mr. W. E. H. Carter is intended as a provisional estimate of the camp. Mr. Carter's judgment is worthy of respect. In addition to his professional experience he occupied for some years the position of Inspector of Mines for Ontario. Consequently, he has an intimate knowledge of gold mining in this province.

NOVA SCOTIAN MINING EXAMINATIONS.

We have been credibly informed that grave abuses exist in the system of examining candidates for coal miners' certificates in Nova Scotia. It is needless to give particulars. We hope that no time will be lost in clearing up what appears to be a distressing condition.

EDITORIAL NOTES.

Our readers will find matter of extraordinary interest in our current London letter. The notes concerning the Maikop oil field, and the discussion of coal dust explosions are outstanding features.

In Canada, gold coins are legal tender for a payment of any amount; silver coins for an amount not more than ten dollars; and bronze coins for an amount not exceeding 25 cents. British gold coins are legal tender, as are, also, subject to certain restrictions, United States gold coins.

The initial number of "Canadian Finance," an independent investment, trade, banking, and insurance journal, has just reached us. "Canadian Finance" is published in Winnipeg under the editorship of Mr. S. R. Tarr. Its object is to serve western interests no less than those of the east. Hence it should be of especial service to thousands of eastern investors. We wish it all success.

Nova Scotian coal operators, as the "Maritime Mining Record" points out, must face the problem of finding a market for slack coal. To our mind the best solution is that of utilizing the slack for generating power at the mine. There are growing markets for power within easy distance of most of the larger mining centres.

The method of measuring ore reserves in terms of the square fathom instead of in tons has been adopted by the Wernher-Beit mines. The change is looked upon favourably by other operators. Why the "fathom" should be chosen instead of the "yard" or, better, the "metre," it is hard to conceive.

HOISTING BY ELECTRICITY.

Where sufficient electrical supply exists and where there is provision to prevent entire stoppage in case of the failure of the power supply, hoisting by electricity is worthy of the consideration of mine managers. At a German mine, where electrical hoisting exists, over 3,000 tons of coal are raised in 16 hours' winding, with an average of 40 hoists per hour.

A SUGGESTION ON "QUARTERING-DOWN" LARGE SAMPLES.

By H. E. T. HAULTAIN.*

I.

(Editor's Note.—These articles were written at the request of the CANADIAN MINING JOURNAL. Mr. Haultain has just returned from a visit to Porcupine. In the articles he outlines his personal opinions in the hope that they will prove suggestive to workers in Porcupine.)

The term "quartering-down" doubtless comes from the ancient and time-honoured method of "coning and quartering," where the ore was carefully shovelled into a cone-shaped heap, carefully flattened out into a pie shape, and as a pie, quartered by two cuts at right angles. Two opposite quarters being discarded, the other two were again carefully coned, flattened and quartered, and this was repeated until a sufficiently small sample remained. This is an elaborate process for mixing and halving and if carried out with care, gives a small sample ready for the assay office, which will truly represent a car-load.

Fig. 1.

The assayer on receiving the sample, which may weigh perhaps 10 pounds, proceeds to crush it to a sand and mixing it thoroughly does the "quartering-down" by means of a riffle-sampler, which divides the sample into eighths or twelfths, preserving alternate eighths and discarding others, and by repeating this he finally retains a sample weighing only a few ounces, but which so accurately represents the original carload as to be the regular basis of sale between miner and smelter. In each case the "quartering-down" is really a halving.

A necessary element of both the coning method and the riffle method is the preliminary mixing, and this is more important where the sample is cut only into quarters than with the riffle sampler where it is cut into a larger number of fractional parts. Brunton, in his presidential address to the A. I. M. E., hsowed that even with the elaborate ritual of the coning method it was easily possible to get false results due to improper mixing. But even where we accept the method as being entirely reliable we are justified in seeking a method less cumbersome; we want something quicker and simpler.

A continuous acting set of riffles, such as the well-known "Jones" sampler, where the sample can be passed through in a continuous stream, or in intermittent shovelfuls, does away with the elaborate mixing, is simple and really fool-proof. Figures 1 and 1A show a very simple form of the riffles adapted for use with the shovel. The discarded material remains in the wheel-barrow and is wheeled away to the dump. In the photo the individual riffles are one inch wide and two inches deep. I have used riffles in this form up to four inches wide, but have of late preferred for large samples a still simpler form of apparatus. Fig. 2 shows a diagrammatical model.

Fig. 1A.

It is simply a plate supported on edge, which splits the thrown shovelful roughly into halves and keeps them separate. The scientific philosophy of this is sound, as is also the horse-sense. What is lacking is the psychological effect of the ritual of the coning and quartering. This method requires no elaborate mixing for instead of dividing into only four parts and accepting two of them, we divide our sample into a hundred or a thousand parts (shovelfuls) and then split each of these parts into halves while they are freely falling in the air. Where there is much work to be done I prefer the form shown in Fig. 3, which is from a photo of a diagrammatical model. The edge is covered with an inverted trough or roof which serves to place the sample away

from the separating plate to make it easier for shovelling, or sends it straight into a wheel-barrow or car. Two splitting edges are used and the sample is shovelled from one to the other and back again, and so on until it is cut down to the required size. Unless the ore has been previously crushed the larger pieces of the sample

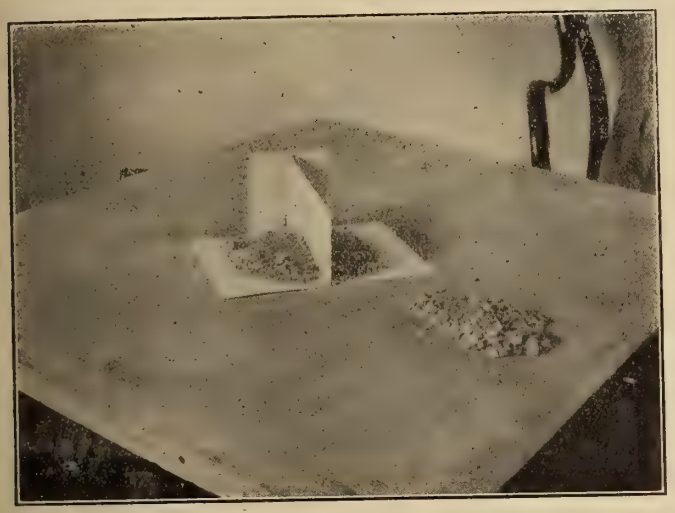

Fig 2.

should, of course, be broken up between each halving. When the sample is down to 25 pounds no piece should be larger than one-quarter inch in diameter. For gold ores showing visible gold freely, the ore should be still finer; a 25-pound sample should be able to pass an 8-mesh screen, and should go to the assay office preferably without a further cut.

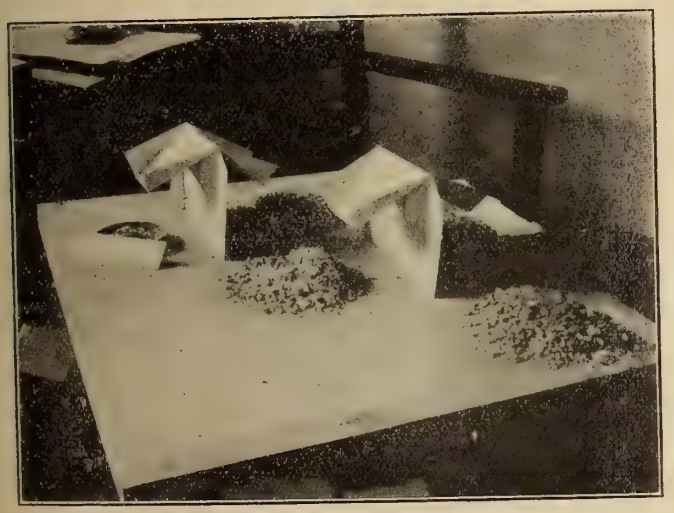

Fig. 3.

The "roof" may be a piece of sheet steel, 3 feet by 6 feet, bent to shape, and should be high enough to admit a wheel-barrow or car under one side. The other side should drop its ore onto a piece of sheet steel, 4 feet by 8 feet, and if the samples are large, a frame or pen of boards 3 feet by 7 feet may be placed upon this to prevent the ore scattering.

*Professor of Mining, University of Toronto.

A NOTE ON THE SAMPLING OF THE PORCUPINE ORE BODIES.

By H. E. T. Haultain.

II.

Porcupine is the most important new district in Ontario to-day. We all want to know what the various bodies of quartz and schist will average when it comes to milling them. It is plainly evident that there is plenty of gold-bearing quartz up there, but it is not yet evident how much of it contains pay values, though we do know that some of it is bonanza ore. Upon the determination of the probable value of the quartz depends the making of some very heavy payments in the near future, and for the purpose of making reliable estimates much work is being done at large expense. Most of the work is systematic and elaborate, the very reverse of that which characterized the early years of Larder Lake. Not only is the surface being exposed by extended stripping and trenching, but shafts and drifts and cross-cuts to explore the bodies at depth are being systematically planned and executed. It is quite true that in some cases shafts have been commenced before sufficient surface work had been done, but it is equally true that some of the surface showings fully justified the expense of underground work without further delay. All this expense is for what purpose? To boom stock? I am glad to say that I do not think so, and to my mind, this is the best symptom in mining in Ontario to-day. This work is true exploration; it is for the purpose of examining the ore bodies and the first thing and the main thing in the examination of an ore body is the sampling, and Porcupine is going to give some trouble with its sampling. So much so is this going to be the case that some people will not be satisfied till they have elaborate "mill-runs" or perhaps "smelter-tests." As a firm believer in the possibilities of sampling and also in the common "horse sense" of sampling, I submit a note or two in regard to the evident troubles. In the first place the quartz is going to be remarkably "spotty," not only spotty inch by inch, but spotty round by round. There are going to be hand specimens and "tie-pins" frequently associated with barren quartz as their immediate neighbour, and there are going to be fairly large blocks of barren or nearly barren quartz followed by equally large blocks of bonanza ore. The gold itself is all the way from fine flour gold to coarse and very coarse, though I saw very little of what might be termed "nuggetty" gold. Incidentally it is worth noting that the gold is certainly "where you find it" up there. It is in the quartz and in the schist, in the seams and in the solid, with the sulphides and in the white, so-called "bull quartz." It is with the fine sulphides and with the coarse cube pyrites. It is with galena and with zinc blende. And also it can equally well be absent from each and all of these associations.

But to come back to the sampling. Can these ore bodies with their very erratic values be sampled? They certainly can be sampled in such a way that the results will be very far from a true guide no matter whether the samples are taken with a prospect pick or run through a mill, but I think they can also be sampled very satisfactorily by adapting general sampling methods to the special conditions, and I have no doubt that sooner or later transfers will be made on the basis of sampling and that careful managers will control their output and report their reserves based on sampling just as is done in all other respectable gold camps.

The values vary greatly from inch to inch across the veins—this calls for increased care in the taking of the

individual samples, and despite this care it will result in greater variations from the probable mean value and consequently calls for more frequent samplings. The values vary greatly foot by foot along the vein. This calls for more frequent samplings. We must never forget that not only do we want to know the general average value, but we also need to study the vagaries of the ore body, wherever visible, that we may better interpret and estimate the unseen. That is the main difference called for—more frequent samplings, added to greater care in the sampling; greater care to more successfully eliminate partiality of motive and partiality of method, and more frequent samplings to permit of the greater chances of error "evening up." There is another aid to accuracy and that is to take larger samples. I don't mean to change our methods altogether and substitute the blasting down of samples of several tons weight for the sample carefully taken by hammer and moil. I mean that the sample should be increased in pounds, not tons, that where we took a 10-pound sample in copper ores we should take a 50-pound sample in Porcupine. But the taking of the larger sample should never for one moment permit us to relax our care in the taking. It is hard to persuade the ordinary man that the erratic results of individual samples do not make all care seem foolishness. They say, If with all your care your results are each very different from the true average why are you so careful? Samples taken at haphazard will not vary to any greater extent. The answer is that other things being equal chances will even up; with great care exercised in each sample to get the right proportions, etc., the errors will balance when many samples are taken. This is true philosophy, it is also horse-sense and everyday experience.

I think it might be very good policy occasionally to satisfy oneself by taking a large sample by blasting down several tons, breaking it up small with hammers and carefully quartering it down, remembering always to break the larger pieces before each quartering, so that we would wind up with, say, 25 pounds of material that would pass a 4-mesh, or, better still, an 8-mesh screen, and sending this 25 pounds to the assay office to be assayed.

Particularly in taking surface samples where the ore has not been shattered by blasting it would be well to jar up the surface by a row of holes 18 inches to 2 feet deep, followed by the taking of a fairly large sample, say one hundred pounds for each five feet of sampling, but let there be no relaxing in the painstaking care of the sampling because of that 100 pounds instead of 10 pounds.

Frequent samples taken in this way will give a very reliable idea of the true values. A few samples, no matter how they are taken or of what size, cannot represent truly the erratic ore bodies in Porcupine.

Personally, I should have very much the greater preference for a system of sampling that "quartered down" every round of muck as it was brought to surface. The extra cost of doing this, that is, the cost above added to the cost of the underground workings, would be small in comparison and the results would be something to swear by. The bucket could discharge over a splitting board, one-half could go direct in a car to the dump, the other half could be broken up with hammers and cut down on sheet steel plates.

Porcupine ores will be new for many assayers. Their final sample should be much larger than usual, they must be keenly alert for metallics, they should crush their final sample through 150-mesh, certainly through 120. They should not work with less than one assay ton and should make their assays in duplicate and triplicate. They should also take duplicate samples of the sample brought to them to check their own methods of quartering and care of metallics. The bucking board must be a good one, free from holes, and the man who bucks the samples will need especial training and overseeing. There are more errors made in breaking down samples than in assaying.

Given proper care and these common-sense precautions, reliable results can be obtained and the only added value of the mill test will be a psychological ore. But there is nothing that will obviate the necessity of skilful care if the results are to be reliable, and skilful care means the expenditure of money, much more money than one is accustomed to see spent on such apparently simple things as sampling and assaying. If the sampling and assaying are not done with elaborate care, costing money, the result will be a poor guide; it will be worse, it will misguide. Mill-tests and long-distance shipments of big samples cost money. My idea of the situation is that money spent on proper sampling and assaying will give very much more information in regard to the values of the ore bodies than the same money spent on mill-tests, but to attempt to sample and assay Porcupine ores in a casual way would be a travesty on scientific methods and on horse-sense.

SOME NOTES ON THE PHILOSOPHY OF SAMPLING.

By H. E. T. Haultain.

III.

A sample is a part to show the quality of the whole. Sampling is the obtaining of that part. In mining work we have the sampling of ore in place, and the sampling of broken ore. The sampling of an ore body, i. e., ore in place, is an art requiring knowledge, experience, skill, and the exercise of relentless care; the best method of procedure varies with the local conditions. The sampling of broken ore is largely a matter of procedure so simple as to be termed mechanical, or else is entirely the work of machinery. It is impossible to eliminate skill from the sampling of ore in place, if the result is to be reliable. The greater the experience and skill of the sampler the more reliable will be the result. On the other hand with the sampling of broken ore, the more that skill is eliminated, and the more mechanical and fool-proof the procedure, provided it is on correct lines, the more reliable will be the result. The reason for this is that the sampling of a body of ore in place is an imperfect method at its best, because only a small part of the ore can be seen and handled, whereas with broken ore the entire quantity can be passed through the process or apparatus. The result of sampling ore in place is an approximation and the skill and experience of the sampler is called into play, first in the obtaining of the samples, and, secondly, in interpreting the results. The sampling of a body of ore in place results in a series of samples, probably of very different value, no one of which may represent the average value of the ore, but which when taken together and properly interpreted will result in a reliable estimate. The sampling of a quantity of broken ore may result in one small sample which is so close and sure an approximation that it will represent the total quantity as accurately as our modern sensitive scales will weigh it. But this small sample will consist of a very large number of pieces or particles of ore, no one of which may represent the average value of the lot, some of which may be many thousands of times as rich as others, but when

taken together (without further interpretation) will accurately represent the original quantity. (The series of samples which represent the body of ore in place may be considered as having a similarity to the particles of ore which go to make up the final sample of a quantity of broken ore.)

The Sampling of Broken Ore.

What is the first essential feature required in the result of the sampling of a quantity of broken ore? Surely the answer is accuracy, and the second feature, fully as important as the first, is that we should know that the result is accurate. There is little use in the result being accurate if we have our doubts about it.

To assure accuracy we must have impartiality of motive in the man and impartiality of method in the procedure. Many think that it is only necessary to have impartiality of motive and will consider a grab sample taken with eyes shut a fair sample. They will say that if you tear a sheet of paper into a score of scraps and throw these into the air over the pile of broken ore then pieces of ore taken where each scrap of paper fell will constitute a fair sample. This eliminates the partiality of motive, but the method is still partial in that it takes samples only from the surface, or perhaps from only a small area of the surface, of the pile. Others will tell you that a large sample is a fair sample and the only fair sample, that there is some special virtue in a two-ton sample sent through a "mill-test." With the value of the "mill-test" I have dealt in a previous article.* The value of the large sample depends on the way it is taken, just as does the small sample. There may be a partiality of method which will completely upset the accuracy of the large sample, and it is generally much easier to protect the small sample from salting than the large sample.

But impartiality of motive and impartiality of method alone are not sufficient to insure an accurate sample; one thing more is necessary. The sample must contain a sufficiently large number of separate particles. If we had 900 one-ounce pieces of quartz and 100 one-ounce pieces of galena mixed together we should have a mixture containing 10 per cent. galena. If the pieces were uniform in weight, then nine pieces of quartz and one piece of galena would be a representative sample of the lot. Fewer than ten one-ounce pieces could not possibly be a representative sample. Nor would there be much chance of getting one and only one piece of galena in a sample of ten pieces by any method of cutting down, no matter how impartial our motives and our methods might be. This extreme care emphasizes the fact that chance or probability plays a large part in sampling, but other things being equal chance evens up in the long run. We must not only have at least ten pieces in our final sample to permit of the mathematical possibility of its representing the 10 per cent. mixture, but we must have a very much larger number to even up the chances no matter how impartial our methods. How many pieces should constitute a minimum sample is not easy to define even by higher mathematics, but it is not difficult to err on the right side if we take the precaution to crush the samples before cutting. One pound of ore crushed to pass a 30-mesh screen will contain many millions of separate particles, and with all ordinary ores, if this is halved by any reasonably impartial method the chances will even up so completely that the most careful assay cannot detect a difference in the value of the two halves. But should the ore contain particles of gold so large that they will barely pass the 30-mesh we have an extreme case calling for special treatment. The assayer recognizes this and where metallics are present screens them out and treats them separately. In a $20-ore one particle of gold in the sample will call for an equivalent of 30,000 particles of barren quartz, each weighing as much as the gold particle, or of more than 200,000 particles of similar size. For this reason the assayer should use a finer screen for gold ores than for other kinds and should watch most carefully for metallics.

In finely crushed gold ores the value of individual particles will vary from nothing up to $600,000 per ton. In coarse particles the values will not run so high, consequently it is not necessary to have so many particles in the large sample of coarsely-crushed ore as in the small sample of finely-crushed ore.

To sum up: Experience based on the work connected with the sale of many millions of tons of gold-bearing ores shows that a car load of ore may be truly represented by a small sample. Where no metallics are present three ounces of 120-mesh material may truly represent the carload of 50 tons.

To get this result impartiality of motive, impartiality of method and sufficiently fine crushing is all that is necessary. The process is generally a series of halvings of the ore, one-half being rejected and the other half again halved and so on. As the sample is reduced in quantity the individual particles are reduced in size by repeated crushings. In regard to the fineness of crushing Richards gives this table:

Size, Inches Cube or Mesh.	Weight of Sample, Pounds.
2 inch	10,000
1 inch	2,000
½ inch	400
¼ inch	200
⅛ inch	75
10 mesh	25
50 mesh	1

Where metallics are present the limiting size of the sample depends upon the coarseness of the metallic particles. In the extreme case of some of the Cobalt ores the metallics are removed before the first cut in the car load is made, and this may be necessary in some phenomenal nuggetty gold ores.

But with the majority of gold ores it is not necessary to attempt to separate the metallics until the sample is reduced to one pound in weight. The criterion is not mathematical deduction, but practical experiment.

If our methods have been correct and yet duplicate samples fail to check sufficiently closely the remedy lies in larger final samples, but it would be a phenomenal gold ore, indeed, of which a car load could not be represented by a few pounds.

Sampling Ore in Place.

In sampling a body of ore blocked out in a mine at best we have only access to certain "faces," the "sides" (more truly edges) of a block of ore exposed by shafts, tunnels, etc. We may be able to see four sides or edges of the block and our ordinary sampling methods with moil and hammer may then perhaps reach as much as 2 per cent. of the ore and the value of the 98 per cent. unseen must be based on the results obtained by sampling the 2 per cent. No rules will govern here. The peculiarities of the ore body must be interpreted by the judgment and experience of the man. In regard to the sampling of the exposed faces, however, the underlying philosophy is similar to that of sampling broken ore.

---

*CANADIAN MINING JOURNAL, Jan. 1st, 1909.

Theoretically the surest way would be to take a slice of uniform thickness from all the exposed face and pass it through the procedure for sampling broken ore. This would give us an entirely true result as far as the average value of the whole face was concerned, but if the face were of varying width and varying value it would still leave us ignorant concerning these variations of value and it is largely on the proper interpretation of these variations that we base our estimate of the unseen ore. If we cut up our slice along the exposed face into sections and sample each section separately, we get information concerning the variations and the shorter the length of each section, within reasonable limits, the more complete our information. Sometimes this can be done, for example, by sampling each round of muck as it comes from shaft or tunnel, otherwise it very seldom is practicable. As a substitute the next best course is to take out small short sections at intervals, and in practice this comes down to cutting a "channel" with hammer and moil. In this we get very far away from the simple, fool-proof procedure of sampling broken ore. The dangers resulting from partiality of motive and partiality of method are seriously magnified. There can be and often is wholly unconscious partiality of motive. A mine foreman knowing his ore intimately and deeply interested in his mine can rarely take impartial samples. Impartiality of method is assailed by the varying degrees of hardness or brittleness of the ore, and less consciously but perhaps more dangerously by sudden variations in apparent value. This sampling of ore faces by hammer and anvil (which is certainly the best method as well as the standard method) calls for experience, sound judgment, skill, care, patience, persistence, more than any other operation that falls to the lot of the engineer. Given all these, given complete impartiality of motive and of method, our final result must be gauged by the weight of the chance. Just as a few particles cannot safely make a representative sample of a lot of broken ore, so a very few sections of an ore face cannot safely represent the whole ore face. I think we can sanely say that one sample taken across a small section of an ore face by itself means nothing. It is only in association with others that it has its value. One sample may be very far from the average value, each sample is probably more or less so, but in many samples the "chances even up" and our average will be more surely correct the more frequent the sampling. This, then, is the mechanical side of the question, as it was with sampling broken ore. There must be many samples of a face, as there must be many particles in the sample of broken ore. But in sampling broken ore we erred easily on the safe side by sufficient crushing. In sampling ore in place we can never get too many samplings. On the same line of reasoning our individual samplings should not be too small. With very evenly valued, disseminated ore small samples may be all right, but the more the ore is spotty the larger should be the sample and also the more frequent.

Increasing the size of the sample is only to be used as an added guard. Many seem to think that the large sample in itself carries the evidence of impartiality.

It is probably the reverse. The large sample may suffer from partiality of method through an excess of the more easily broken part of the ore, or from partiality of motive from being taken by blasting from a richer (or poorer) part of the ore body. There may easily be specimen car loads as well as hand specimens. *Frequency of sampling is of much greater importance than increase in the size of the sample.*

In conclusion, there is no royal road to the sampling of ore in place, as there is no mechanical road. Impartiality of motive and of method are the first essentials but to these must be added all the human attributes included in experience, skill and care, and to all this must be added frequency of sampling to appease the Goddess of Chance. The one exception to this, the only approach to the mechanical and the fool-proof, is to sample by suitable halving methods all the muck as it comes from each round blasted in shaft or tunnel or cross-cut.

THE AMENDMENT TO THE CRIMINAL CODE.

Following is the text of recent amendment to the Criminal Code. It relates to ore-stealing:—

An Act to Amend the Criminal Code.

(Assented to 4th May, 1910.)

His Majesty, by and with the advice and consent of the Senate and House of Commons of Canada, enacts as follows:—

1. The Criminal Code, chapter 146 of the Revised Statutes, 1906, is amended by inserting the following section immediately after section 424:—

"424a. Everyone is guilty of an indictable offence and liable to two years' imprisonment who, having in his possession, or upon his premises, with his knowledge, any rock, ore, mineral, stone, or quartz of a value of not less than twenty-five cents per pound, or in the case of mica of a value not less than seven cents per pound, or any partly melted, partly treated or partly manufactured gold or silver which there is reasonable ground to suspect has been dealt with contrary to the provisions of paragraph (b) or (c) of section 424, is unable or refuses to account satisfactorily for or prove his right to the possession of the same.

"2. If in any proceeding under this section any question arises as to the value of any rock, ore, mineral, stone or quartz, the judge, magistrate, justice or other officer before whom the proceeding is pending may order such assay or assays, test or tests, to be made as may be deemed requisite for determining such value.

"3. No action or prosecution for a violation of this section shall be commenced or undertaken in any part of Canada unless or until an order has been passed by the Governor in Council declaring this section to be in force in such part of Canada. Any such order may be amended, revoked or renewed from time to time in whole or in part by any subsequent order in council.

"4. No prosecution shall be had under this section unless it had been initiated on the information or complaint of a manager or director of a mining company or on the information or complaint of some one thereunto authorized by a mining company or a manager or director thereof, or by or with the authority of the attorney-general of the province in which the offence is alleged to have been committed, or by the owner or part owner of a mine who deposes under oath that he believes that rock, ore, or other substance similar to some of those mentioned in this section has been stolen or wrongfully taken from the mine."

The use of steel square timber sets is estimated to reduce the timber cost per ton of coal mined in certain anthracite regions from 7.7 cents to 5.7 cents per ton.

THE PORCUPINE GOLD AREA.

By W. E. H. Carter.

Having heard many favourable reports of this recently-opened-up district the writer determined to see for himself what the new discoveries of gold amounted to. The trip was made about the middle of May and nearly two weeks were spent in looking over the properties on which the most important finds to date had been made. I am glad to be able to say that the showings of gold-bearing quartz on some of these properties justify the earlier information given out, and promise to develop into important paying mines.

Vein on Dome.

Several articles have already appeared in the Canadian Mining Journal on this new mining camp, which give some information of the geology of the area and the veins, the topography and general character of the surface, and also of the routes by which access is gained, so that there is little left to note in these connections.

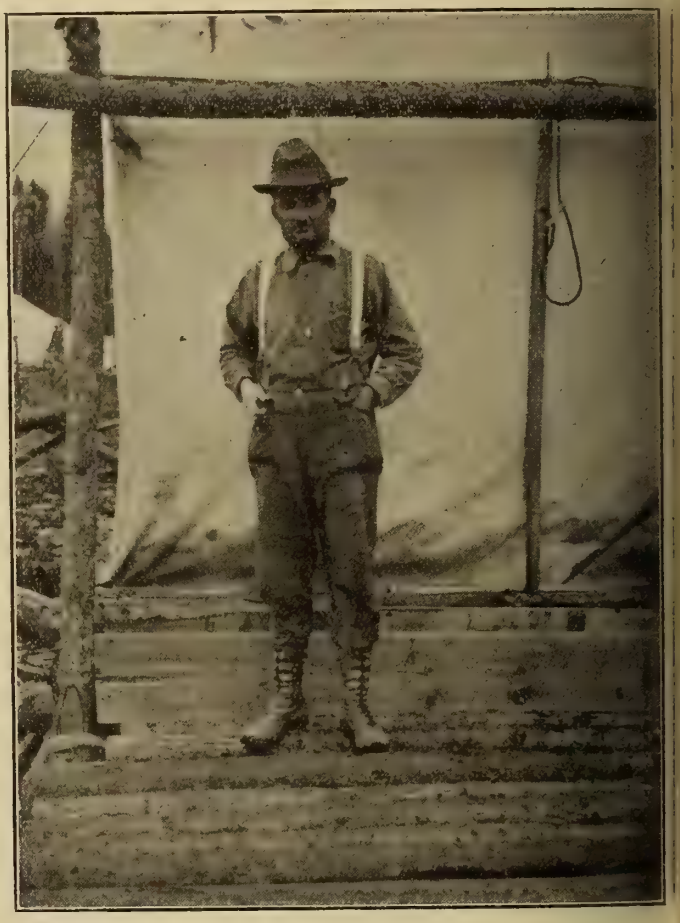
With regard to the geology it is of interest to know that Dr. W. G. Miller, Provincial Geologist, is now on the spot with three parties, all of them actively engaged gathering data for a geological map of the townships of Whitney and Tisdale, in which the most important finds of gold have been made, and of probably a portion of the country adjacent round about these. It is hoped to have this information ready for distribution before the first of August, and it will be of value in clearing up much of surmise as to character and relation of the rocks and veins of the area.

In hilly, rocky countries the casual traveller or prospector might easily form some correct conclusions for himself, but not so here where the surface of the land is flat and for the most part covered with clay and sand with a top dressing of wet swamp and dense spruce forest. The rock exposures throughout are widely scattered and then usually only low ridges of quite limited area well covered with moss and timber.

When the first general survey of this country was made by the writer for the Provincial Bureau of Mines in 1898, exploration was confined to the rivers and lakes and the country for a mile or so back therefrom

on either side, from the height of land at Night Hawk Lake and Porcupine Lake to tide-water at James Bay and, although all these creeks and lakes that are now the scene of mining activity were then surveyed and mapped, so few rocks were observed (all apparently of Huronian Age) that the whole area from this point north for a good many miles, was considered as belonging to that geological period. With the present more detailed examination by prospecting, it appears that while there are large areas of Huronian in the shape of dark greywacke schist, the Keewatin green schists are

Vein on one of the Dome Claims.



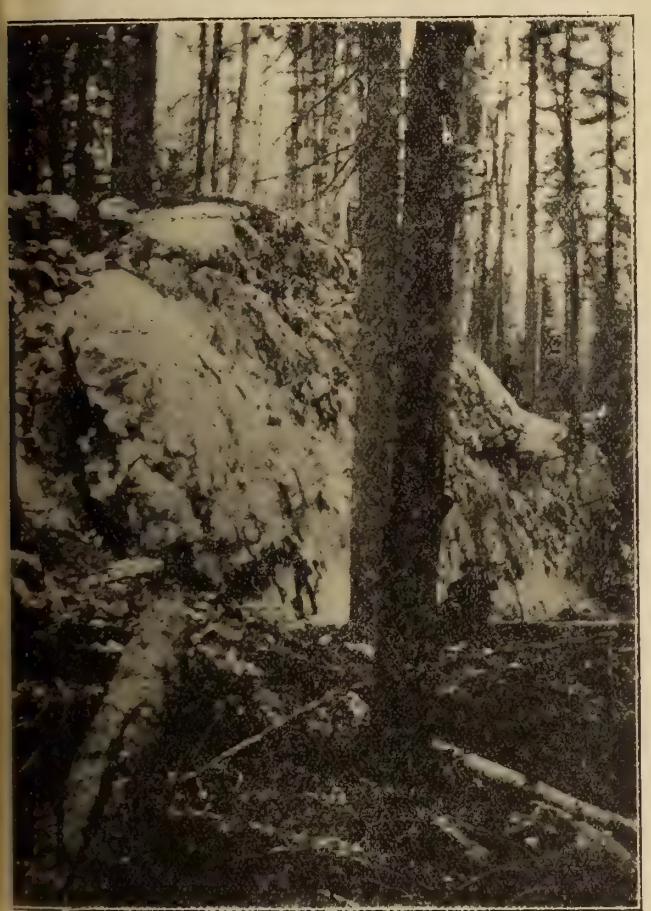
Typical Outcrop on low wet Ground.

also well represented. These two appear the most frequently and contain the present important veins. Other reported rocks consist of quartzites, some basic eruptives and conglomerate.

The veins are lenticular in character and irregular in width. In one case the quartz covers an area of approximately 100 feet by 100 feet, with some country rock intermixed, but this is exceptionally large. Most of them range from 5 to 10 feet, with occasional still greater expansions. The few that have been stripped for any length maintain, generally, a uniform strike for that distance, over 500 feet in one case and 300 feet in many others. There does not appear to be any one favoured direction nor do they necessarily run with the formation.

The veins are of solid white and, in a few cases, blue quartz and are ideally free milling. The quartz itself contains only a very small proportion of metallic sulphides, probably under 1 per cent. and that mainly iron pyrites, but also specks of galena, blende and chalcopyrite. It is tough to drill, but crushes readily. The walls close to the vein and also the inclusions of the same country rock in the quartz between the walls are on the other hand very highly mineralized with iron pyrites in crystal form, and as much of this will have to be milled with the quartz, the percentage of sulphides will be thereby somewhat increased. No weathering and oxidation has taken place beyond a few inches to a foot below the surface in the veins.

Wilson, Discoverer of the Dome.



The first important discovery of gold is said to have been made in the southern portion of the township of Tisdale on the Wilson-Edwards claims, or, as they are now called, the Dome Mines. This was quickly followed by others in the same neighbourhood. The time was about the middle of last summer, and the rush of prospectors which followed has resulted since in the complete staking of the country for a number of miles in every direction. These same pioneers are now migrating still farther west beyond the Mattagami River, which lies a short distance to the west of Tisdale Township. Naturally, considering the distance from source of supplies and the long winter, but little development work has been as yet accomplished on any of the claims, and not until the end of the summer or later, with active stripping and other mining operations, will it be possible to form an idea of the extent of the pay ore

ea in the countless claims outlying the best finds of t day.

The most striking feature of the field is the great mber of quartz veins being found. Almost every day ring the spring months new ones were uncovered, t only on hitherto untouched claims, but on those der active development, where already many had en laid bare. One wonders where it will end. Ordirily such a condition of affairs causes fear that the ld will be found too widely distributed in small quanies and, consequently, insufficiently concentrated in y one vein or group of veins to produce pay ore. Such s been the history of more than one gold-bearing field Ontario.

tions in the best of the veins. This remains to be determined in the course of development by systematic sampling and assaying, little of which had as yet been undertaken.

On this particular group of claims a shaft was being sunk, then 60 feet deep, across the whole width of about 15 feet of the vein. Judging from the dump rock therefrom the quartz is remarkably rich, possibly $200 per ton for the whole dump. Say, however, that it only averages $100 per ton, the three hundred tons or so now in the pile represent $30,000. If this can be repeated for even a short distance of vein at the same depth the values mount up into extraordinary figures. Adding to this the fact that there are, with almost no explorat-

Another View of Outcrop on Timmins' Claims.

Trenching in Swampy Country. (Foley-O'Brien lease.)

However, this time there appears little doubt that the ception has been found. There is a group of claims ar the southwest corner of Tisdale township which robably hold the record in the camp for number of ins at short distances apart, and in every one of them ld can readily be seen in many places. Knowing the ld areas of Ontario so well, where it has been typical find large scattered nuggets of gold, and then rough the remainder of the vein practically nothing, was of particular interest to be unable to find, here anywhere in the camp, such specimens. On the conary the gold is finely disseminated, even in the richest mples. This is the most encouraging feature of the ins, for it indicates the likelihood of a better distrition of values throughout the quartz in those places here none can be seen.

Doubtless there will be pay shoots and barren portory work done, a dozen or more quartz outcroppings on various other parts of the property, some of which have equally good surface showings, one may arrive at some conception of the possibilities. The veins were never less than 2 or 3 feet wide, and from that up to 15 and 20 feet, roughly averaging, as then uncovered, probably 6 to 8 feet wide.

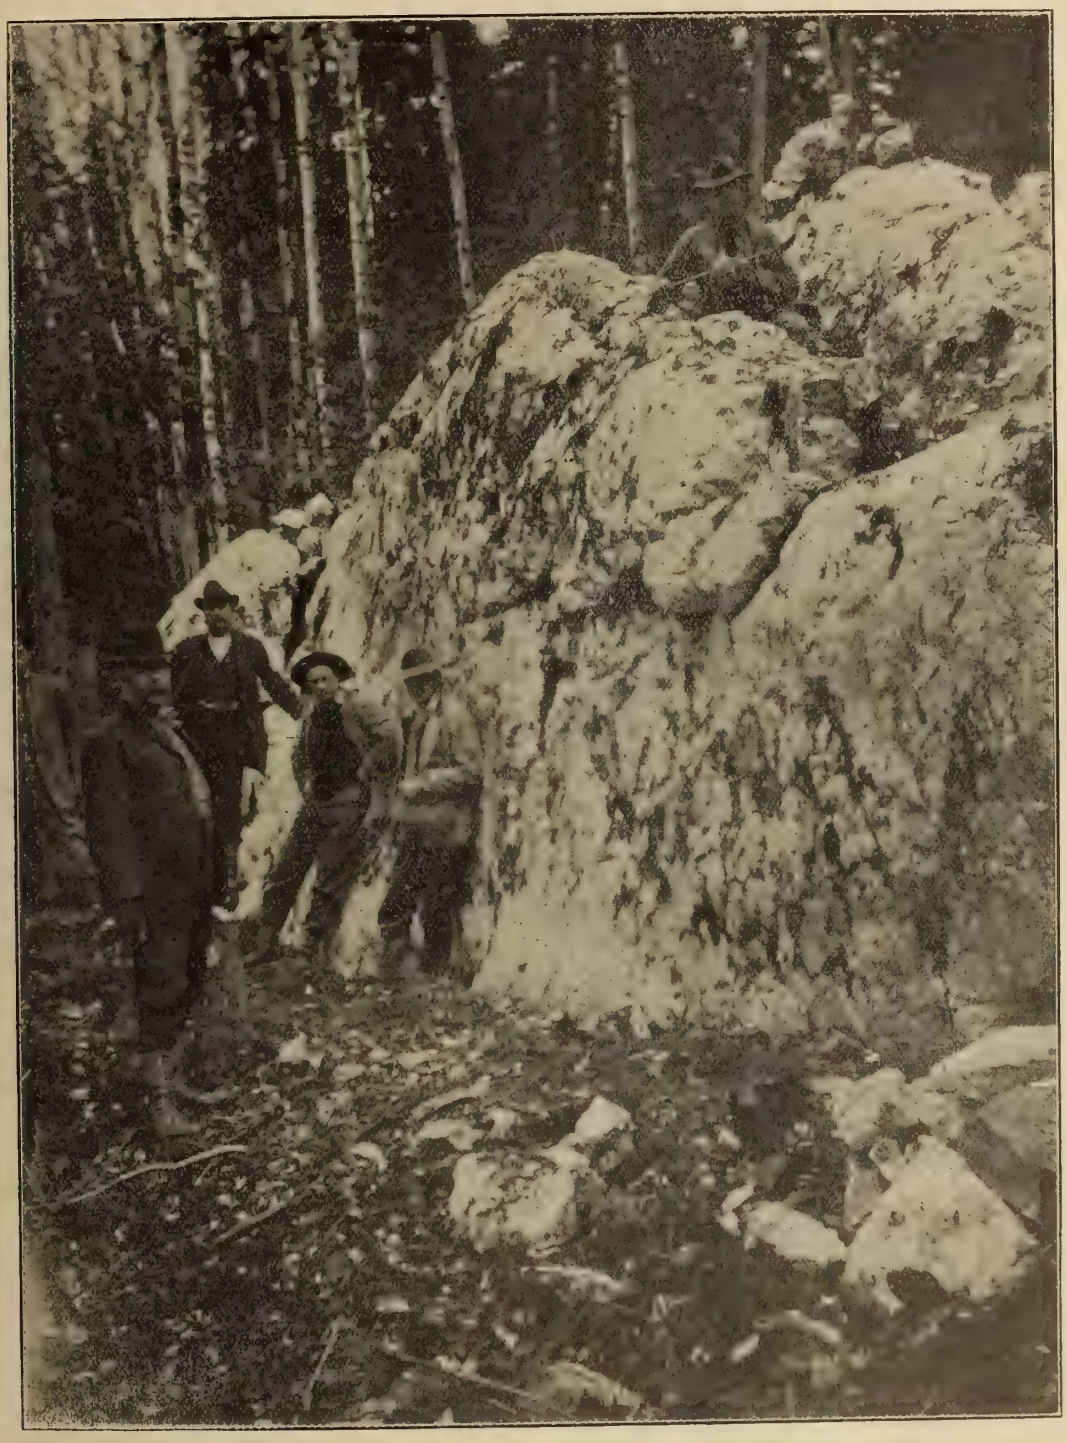
Without as yet actually knowing the gold content of these several veins it is not likely that as mined they will average any such figure as that of the ore from the above mentioned shaft. But with such apparent quantity a much less average value per ton will suffice to make of them a most profitable mine.

There are several other properties, usually in each case a group of claims on which it has not been so easy to strip the surface and, therefore, less is known about them as yet. Much the same conditions prevail on all

of these, however, as regards number of veins, but as to the quantity of gold they contain not so much is as yet known.

From what was seen it is not too much to expect that the area will produce several paying gold properties, one of which, at least, will be remarkable for the amount of gold taken out.

These better properties have not been acquired by the present owners, or optionees, for a song. Far from it Prices paid were abnormally high. In almost any other field they would be considered not only prohibitive, but absurd. Most of the claims with showings of auriferous quartz not yet sold are held at such high prices (considering that practically nothing in the way of prospecting and development has been done on them) that investors have held back and will no doubt continue to do so until they can see a chance for their money.



Vein on Porcupine Gold Mining Company's Property. (Flynn's Option.)

The best showings to date are confined to the southern half of the township of Tisdale with an extension into the northeast quarter. There were reports of finds of gold in the outlying areas, but no work of account had been done on them.

In justification of the high price the prospector or other owner asks a comparatively small sum down will

ıne to work, but the latter is generally insufficient. It difficult to get in supplies and men and requires more me and money for this rush development than in more ccessible regions.

The high prices paid in the silver camps to the south ave without doubt upset all idea of reasonable values investors from visiting the camp, and for the same reason the public has not yet realized its importance. On the whole this is not a bad condition. The trip to-day is very hard for one not accustomed to the bush, as he must walk more than twenty miles, half of which is through swampy country on a winter road. If the

An Outcrop on Timmins' Claims.

ınd terms. As a result the public have stood away to a serious extent. This fact the claim owners have not as yet realized. They may too late. It is better to make sure of a reasonable sum, particularly when the buyer is expected to make all the discoveries and assume all the chances, than to hold out for a fortune and lose all.

The difficulty of access to it has kept many possible rumoured line of transportation in from Bisco on the C. P. R. via the Mattagami River materializes as outlined, one will be able to reach the camp by steamers and over portages by automobile. It would be well worth the trip to enjoy the scenery along this route.

The present route is from Kelso on the T. & N. O. Railway, past Frederickhouse Lake and Night Hawk

Lake, about twenty miles of walking and fifteen by gasoline launch. The trip is made in a day, with arrangements for the passenger already well organized. Not so, however, for freight, which it is very difficult to get in at all, and then at a cost of $6.00 per hundred from steel to Porcupine. Some improvement in this may, however, be expected as the summer progresses.

camps to the south. Miners receive $2.75 to $3.00 p day, with 25 cents per day added for shaft work; hel ers about 25 cents less, and surface men $2.50, all cle The demand was greater than the supply at the ti of my visit, particularly for foreign labour which is t most suitable for trenching operations.

A kind of telephone line has been strung on tre

Timmins' Shaft. Outcrop on extreme left looks like Dump.

Towards the end of May there were about 500 men at work for the larger outfits. In addition probably half that number were scattered throughout the area doing assessment work. Prospectors were arriving in considerable numbers every day, the majority travelling to newer fields in the neighbourhood of the Mattagami River and west.

Higher wages are paid here than in the more settled from Matheson in to Porcupine and continues to a fe of the mines. Occasionally it gets out of order, bu messages may be sent right through with a fair certai ty of their arriving without much delay.

A bi-weekly mail service takes letters only, but a improvement is expected shortly whereby all classes c mail will be carried more regularly and more frequen ly.

RUBBER AND OIL DISTRACT INVESTORS' ATTENTION FROM MINES. THE TROUBLES OF MAIKOP. NEW TRINIDAD AND CANADIAN OIL FLOTATIONS IN LONDON. THE CUMBERLAND MINING DISASTER. COAL DUST EXPLOSIONS AND IGNITION BY ELECTRIC FLASHES. EARTHED VERSUS INSULATED NEUTRALS IN COLLIERY INSTALLATIONS. SOUTH WALES COLLIERIES UNITING. BIG ENGLISH TIN MINE SHAFT. PURE AIR FOR RAND WORKERS.

Exclusive correspondence to the "Canadian Mining Journal.

London, May 18th, 1910.

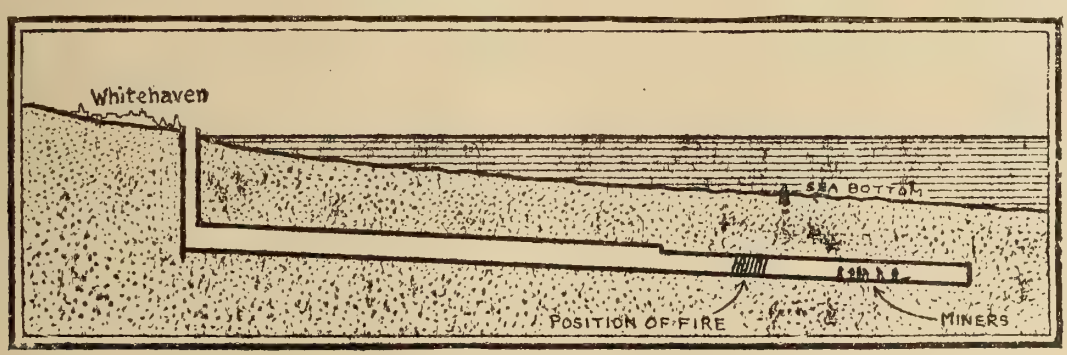
Mining shares on the London Stock Exchange continue to rank as second favourites to rubber and oil. Despite this reports from the mining fields speak o progress almost everywhere. The Rand, helped by in creasing labour supplies, has maintained its phenomen al prosperity. One giant company, for example, Ran Mines, has paid its shareholders a total dividend of 35 per cent. for last year. Many new stamps are to star crushing during the next few months. Sensational dis coveries of great promise continue to be made in Rho desia. In West Africa developments are favourable i the extreme, and there are very far from being an signs of waning prosperity in Australia.

Still the attention of the investor is for the momen given elsewhere although in connection with the Mai kop oilfield the market shows some signs of sufferin from the absence of any definite news of an encourag ing character. Six months ago a spouter was tapped which gave out such a quantity of oil that it becam

necessary to stop the flow in order to prevent the surrounding area from being devastated. Even as it was, the rivers in the district were polluted and a large quantity of fish destroyed.

The present difficulty is not to discover other similar deposits but to avoid any step which would bring about a repetition of last year's experience. In other words, a good many spouters could be tapped at very short notice if required, but preparations for storing the oil are not yet complete.

The damage wrought by the spouter already referred to, was a very serious matter for the owners, as the Russian Government came down upon them for compensation, and I understand that the original proprietors of the property were ruined as a consequence. It may be taken, therefore, that the absence of any news regarding further discoveries of oil is due not to the inability of the officials at Maikop to announce further discoveries, but is attributable to the necessity of first of all installing a sufficient storage plant to cope with the supply.



At present the only storage accommodation afforded those companies which have already tapped spouters, is that of the ambaars, or uncovered pits. Now, under Russian mining law, the storage of large quantities of oil in this way is absolutely illegal. Thus, pending the completion of iron reservoirs—the only comparatively safe means of storing oil—the companies which have achieved the preliminary success of finding oil are compelled to keep their wells capped. For the present actual production is limited to one company—the Black Sea Oilfields, which is getting all the oil it requires for the purposes of its local refinery from a small 2-inch pipe tapping No. 2 well, which is, of course, capped.

Meanwhile, it must not be assumed that work at Maikop is at a standstill. Boring operations are proceeding at an energetic pace, and I understand that by the end of the year the number of wells on the field will be not less than eighty. By that time, if not before, the establishment of iron reservoirs will be well advanced, and the first pipe line—that connecting the field with the railway which communicates with Touapse Port, will be laid. Thus, within, say, another nine months, Maikop should have begun to settle down in earnest as a big oil-producing district, and for geographical reasons, if for no other, it is not unlikely to beat Baku as an exporter, though the older field will still, probably, remain the chief supplier of oil to the native consumer.

As regards the Trinidad field, a district to which several recent flotations have directed attention, documents exist which appear to indicate that the deposits are of exceptional value as regards both quantity and quality. The oil is of several grades—that is to say, here is a large deposit suitable for fuel purposes and others of lighter quality. Some of the largest oil consumers in the world are making business arrangements in connection with the Trinidad field, and the outlook for companies operating or about to operate in this district is regarded with every confidence by those concerned. The present set-back in the share market is not taken seriously, but merely as a temporary matter, attributable to the excessive activity recently noticeable, and a recovery is anticipated before very long. Several important propositions have still to make their appearance, and may be expected during the next few weeks.

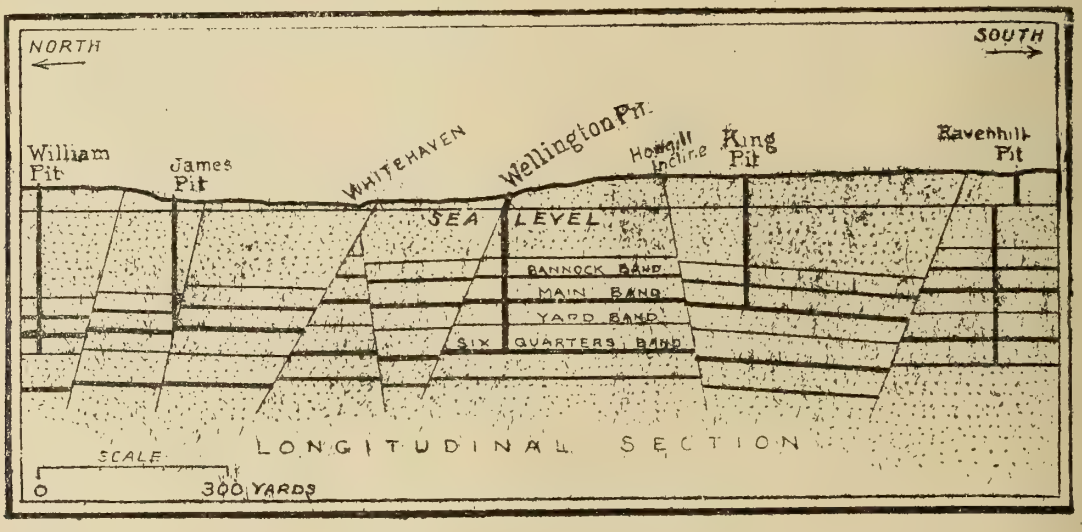
Canada also has made her appearance with several oil companies, the biggest being the Canadian Oil Producing & Refining Company, which has a total authorized capital of $625,000, and has been formed to acquire oil lands at Petrolia, Ontario, and elsewhere. It has emphasized its claims as "an oil-producing company with ample plant in the British colony—a growing concern."

Although the Cumberland mining disaster was probably due to another cause, it has revived discussion of the subject of coal-dust explosions in mines. It may, therefore, be useful to draw attention to certain facts relating to such explosions. In the first place, the dust must be raised into a cloud before it will explode; when in bulk it is not dangerous. A blown-out shot will, of course, do this, and no doubt under certain conditions the exhaust from air-drills or other mechanical disturbance would be sufficient to stir up a dangerous cloud, and in any case the advance wave preceding the flame of an explosion will stir the dust up. Once stirred up it can be directly ignited by an ordinary naked light as well as by the flame from an explosive.

Also there is good reason to believe that it is possible, although not generally likely, for the dust to be fired by the momentary rise in temperature caused by the passing of an intense sound-wave such as that from a shot. No stone-dust zone would form a barrier against this last. As regards the suppression of coal-dust explosions, isolating with stone-dust is most strongly favoured at present. Watering is perhaps the simplest method, but, apart from health considerations, it is liable in some ground to increase the risks of falls of roof, and these kill eight times as many as coal-dust and gas explosions together. The efficacy of stone-dust isolation seems fairly proved, provided the conditions are right, for it must be remembered that the explosion flame from a coal-dust zone can be projected several hundred feet into the stone-dust zone. In any case isolation only restricts the magnitude of the explosion and does not ensure that those outside the explosion zone shall not be cut off from safety, as at Whitehaven.

A paper by Dr. Thornton and Mr. Bowden on the ignition of coal-dust by electric flashes was read at

Newcastle recently, which is interesting at the present time in view of the fears expressed as to the safety of electricity in coal mines. The experiments showed that dry coal dust in bulk was a non-conductor of electricity, but that when made into a paste with water it was liable to cause a short-circuiting flash if placed between electrodes. If a flash was produced—as by opening a switch—in a cloud of dust an explosion was produced. The character of the dust-cloud and the strength and voltage of the current broken affected the readiness with which the dust ignited, and at medium voltages direct current appeared to be more dangerous than alternating.



In view of the conclusive experiments on coal-dust explosions produced by the discharge of a cannon, as carried out at Altofts, the results obtained by Messrs. Thornton and Bowden were to be expected. It would, however, be unwise to jump to the conclusion that electricity in mines is a very dangerous thing. It is all a question of the immediate local conditions, and these are rarely such as to encourage an explosion of coal-dust. Indeed, it has been stated that no serious explosion has been produced electrically, and certainly the danger from shock has been much more in evidence. Of course, it is desirable to sift the whole question thoroughly with a view to safety, but the use of electricity in mines promises to do so much to improve conditions for the miners themselves, and also to effect economies in working, that it would be regrettable if ill-considered restrictive regulations were introduced.

Great interest has been aroused by the paper read by Wellesley Wood on "Earthed versus Insulated Neutrals in Colliery Installations." Mr. Wood disclaimed any sympathy with the present scare in regard to the use of electricity in mines, but urged the necessity of considering how accidents could and might occur. He said that the number that actually did occur was extraordinarily small considering the present widespread use of electricity and the insufficient electrical staff employed in many collieries.

His lecture was mainly upon the question whether a three-phase colliery installation should work with an earthed or with an insulated neutral. Not only are there a number of supporters of both systems, but there are also a number of long standing examples of each system at work both on high and medium pressures and with current taken in some cases from a supply company, and in others from their own generating plant.

He summarized the advantages of earthed insulators as follows: (1) Maximum potential to earth of any phase limited to 58 per cent. of line voltage; (2) leakage to earth probably resulted in isolation of the damaged circuit; (3) leakage tripping devices could be used, which switched off the supply when an earth occurred on one phase, reducing danger of shock and explosion. The advantages of the insulated neutral were: (1) Danger of shock and explosion was reduced, as contact with earth and one phase did not complete the circuit; (2) an earth on one phase did not cause an interruption of supply; (3) stress on insulation under normal circumstances was less, and the liability of flashing to metallic casings was considerably reduced; (4) only two-strip coils instead of three, were required to protect each circuit where an automatic switch was installed.

South Wales colliery shares have been strengthening lately and it is generally anticipated that 1910 will show better results than 1909. Numerous rumours are afloat respecting amalgamations of various Welsh coal undertakings. One absorption scheme which has gone through will leave the combined undertaking able to produce about one million tons of coal per annum.

England's famous tin mine—the Dolcoath—has now its new shaft completed. This is 3,000 feet deep, vertical from the surface, is lined throughout its entire length with 9-inch brick, and is 17 feet 9 inches in diameter, inside measurements. It is the finest piece of work of its kind in the west of England.

Pure and invigorating air supply to workers has now become a practically accepted condition of Rand mining. The excellent installation of the East Rand Proprietary Mines has been followed by the adoption of fans at the Cinderella Deep and Village Deep properties. At the Cinderella Deep a Capell fan, an appliance which, among others of various makes, has been known for years in England, was erected during the past year. It has a discharge capacity of 50,000 feet of air per minute, and was adapted to the existing scheme of ventilation by natural means. Since the installation of the artificial ventilation the temperature in the mine has appreciably fallen, and the atmosphere is probably purer than in the case of nine out of every ten outcrop mines along the reef.

The efficiency of both white and native underground employees is said to be exceptionally high, thus indubitably proving that the depth of the mine has no effect on the ability of the men to get through a normal amount of work without undue exertion. Mr. Girdler-Brown, the manager, has, in view of his surroundings, made a particular study of the question of the possibilities of deep level mining, especially since the installation of the ventilating fan, and he is absolutely confident that the probable limit which was put forward a year or two ago, of about 7,000 feet vertical depth, for practicable mining operations, is a good deal short of the mark, and that, with the addition of subsidiary ventilation fans at lower depths, it will be possible to pursue mining operations without abnormal difficulty at a vertical depth of at least 10,000 feet.

RESCUE APPARATUS IN COAL MINES.

(Reprinted from the Weekly Times, Engineering Supplement, May 27th.)

The recent terrible colliery accident at Whitehaven, causing the loss of 136 lives, has drawn attention to the tardy recognition of the necessity for providing breathing apparatus immediately available for rescue work. On this occasion a delay of 30 hours occurred before the arrival of rescue apparatus, and there is reason to believe that, had this been at once available, the fire which followed the explosion might have been reached and extinguished, and many lives saved. It is true that except with a recollection of the fact that the employment of breathing apparatus with a view of saving life after colliery disasters has been hampered by the constantly recurring element of delay, the record of its success up to the present can hardly be looked upon as encouraging. It is manifest, however, that the system has not, on this account, received as yet a fair trial. The success of a rescue party, like that of a fire brigade, depends upon the speed with which the apparatus can be brought to bear upon its object, and the Whitehaven disaster will not have been all of evil if it has the result of converting colliery owners generally to the view that, to be of service, there must be a rescue station within easy reach of, and trained men at, each colliery.

The first report, issued on May 30, 1907, of the Royal Commission on Mines, which was appointed in 1906, dealt exclusively with breathing appliances, and the Commissioners stated that, after fully considering the results of experience in this country and abroad, they were of opinion that the question was ripe for further development, and demanded the serious attention of the industry, though they came to the conclusion that sufficient advance had not up to that time been made in Great Britain to justify a recommendation making the provision of breathing appliances compulsory. Mine owners were, however, urged to take steps toward their introduction.

In their second report, issued in July, 1909, the Commissioners became more emphatic. They said: "We have come to the conclusion that the provision and use of breathing apparatus should be general throughout the country and that every mine should either be provided with a properly trained brigade of its own, which appears to us the best arrangement, or have the right to call for a sufficient number of equipped and trained men from a rescue station." But in spite of this expression of opinion the question is still left entirely to the industry, the State neither requiring the provision of rescue apparatus nor facilitating its introduction at the mines. Still a certain amount has been done. Three central rescue stations have been organized and equipped in Yorkshire at Altofts, Tankersley, and Wath-on-Dearne respectively; one has been provided in Lancashire at Atherton, and one at Newcastle-on-Tyne in connection with Messrs. Armstrong, Whitworth & Company's Elswick works, available for Northumberland and Durham. A scheme has been projected in South Wales to embrace 13 stations, one of which has been erected at Aberaman and another at Crumlin; a central station is to be erected at Cowdenbeath for the Fifeshire and Clackmannan coalfields; and a central station is being organized in conjunction with the experimental mine at Birmingham University. The expenses of these stations are borne entirely by the coal owners, without any assistance from the State. The Home Office, however, has arranged for a conference with colliery owners next month, with the object of seeing how ambulance work and rescue appliances can be improved and systematized.

That greater progress has been made in some foreign countries is indicated by a summary of the situation by Mr. Henry Briggs, which appears in the "Colliery Managers' Pocket-book" for 1910, and gives particulars of the attitude assumed by the various Governments in regard to the provision of breathing apparatus.

In the United States of America it appears that the subject has been taken up, officially by the Mine Accidents Division of the Technology Branch of the United States Geological Survey, four stations having been erected, while nine others are contemplated, and privately by large corporations, as the Frick Coke Company and others. Compulsory legislation is in the hands of the individual States, but no general movement towards it appears to have been made. In Canada no compulsory legislation has been passed. The Dominion Coal Company has established a large and successful station.

In Germany the utility of breathing appliances is widely recognized. In the Dortmund district over 690 and in the Breslau district 673 sets were ready for use at the beginning of 1908. In the inspection district of Breslau, Upper Silesia, by a regulation dated January 18, 1900, at least two apparatus must be provided for every mine working true coal or lignite, the Government engineer being empowered to order an increase in the number if need be, while the managements of the mines are made responsible for the upkeep of the apparatus, and are also obliged to see that a sufficient number (not specified) of trained miners are always available to use it. In the inspection district of Bonn, Saarbrucken, and Aix-la-Chapelle, by a regulation dated May 1, 1907, two apparatus have to be provided for every mine working, and must be kept at the mine, or at a station from which they are quickly available; while the managements are again held responsible for their upkeep. In Alsace-Lorraine similar instructions were issued in May, 1905. In the Kingdom of Saxony, by a regulation made in January, 1901, breathing apparatus and electric lamps (no number specified) must be kept at all collieries. Several neighbouring mines may affiliate, under the approval of the administration, to form a central station wherein to keep the apparatus.

In Austria, the regulations, made in June, 1908, for the Brux district of Bohemia, require respiratory apparatus to be provided at every mine, and to be kept in good order in a depot in the immediate vicinity of the pits. Only the Draeger, Meyer (Westphalia), Giersberg (new type), and Pneumatogen apparatus are permitted, though apparatus of new design, or improvements on old designs, can be used on authorization being obtained from the head mining office of the district (Berghauptmann-

schaft.) Permitted apparatus are divided into two classes. Those of Class I. must allow of work being accomplished with them for a period of one and a half hours; those of Class II. for at least one hour. Precise regulations are issued fixing the number of apparatus and accessories which must be maintained in working order in different classes of mines and also detailing the equipment of the rescue stations and the organization of the men who are to use the appliances.

In France, since April, 1907, it is obligatory to provide breathing apparatus at all mines which employ more than 100 persons underground in the largest shift. In gassy mines which are in connection with a central rescue station the number of appliances at each mine may be reduced to two; otherwise the number must be at least two for the first 200 underground workmen on the largest shift, plus one for every 200 men above the first 200. No mine, however, is required to keep more than six appliances. In each non-gassy mine two apparatus have to be provided. The number of appliances at a central station is determined on the same system, having regard to the largest pit of the group, providing that there be not less than one apparatus per 1,000 underground workmen in all the affiliated mines; but no station need contain more than 20 sets. The central station must be able to furnish at least ten trained rescuers, or as many rescuers as there are apparatus in the station. The apparatus at the mines must be kept in depots within easy reach, and under the charge of authorized persons; and the number of trained rescuers in connection with each depot must be at least double that of the apparatus kept there, and must never be less than eight. They should be distributed as equally as possible among the shifts, and live as near as possible to the mine, and at least one-quarter of all underground employees should b eable to use breathing apparatus to assist the trained rescuers.

In Belgium, since June, 1908, rescue depots have to be provided at all collieries classed in the second or third class of fiery mines, the number of appliances in each depot being one for every 200 underground emplooyes, providing there are not fewer than five appliances at a depot; but there is no need to provide more than ten at any mine. The apparatus must allow of the wearer stopping at least one and a half hours in an irrespirable atmosphere. Each depot must be provided with the stores necessary to ensure the possibility of keeping all the apparatus therein at work for at least 48 hours. At least four workmen must be trained as rescuers for every apparatus provided, these men to be distributed among the shifts, to live near the mine, and to exercise periodically. The Ministry may authorize the formation of a central rescue station for neighbouring mines. The number of apparatus at such a station must be one for every 200 underground workmen at the affiliated mines, but must never be less than ten, though it never need be more than twenty.

In Holland the number of apparatus to be provided at a mine must be at least 2 per cent. of the number of men in the largest underground shift; 50 per cent. of these apparatus must be of the "diving helmet" type, air being blown in through a tube. The number of trained rescuers is left to the discretion of the owners.

In Russia since March, 1907, a rescue corps has to be provided at every colliery. In every mine affiliated with a central rescue organization the number of rescuers must be at least 4 per cent. of the largest shift. For every four trained rescuers there must be at least one breathing apparatus and one electric lamp, but at each mine there must not be fewer than three complete apparatus. In mines not affiliated with a central statio the number of rescuers comprising a corps is determine in the same way, providing that there are not less than si such men. For every three members at least two breath ing apparatus and two electric lamps must be provided At mines in which there are fewer than 50 men at wor the corps may consist of only three men with two ap paratus and lamps, providing, first, that the inspector' approval is obtained, and, secondly, that such a mine i within 5,250 feet of a mine having a normal sized corps if connected by telephone, or within 3,500 feet, if not s connected.

SAFETY CHAMBERS IN FRENCH MINES.

The use of safety chambers is not very common i French mines. Such chambers consist of galleries, gen erally "blind," the entrances of which are provided wit an air lock and in which is stored compressed air at suc a pressure as to prevent the inflow of deleterious gases

The value of such chambers has just been practicall proved by the Compagnie des Charbonnages of Singles in the centre of France, whose experience seems likel to commend their adoption to other companies which u to the present have been holding back. The works a Singles consist of a main shaft 288 metres deep, fro the bottom of which runs a cross gallery 388 metres long About two-thirds of the distance along this gallery a sec ondary shaft has been sunk to 312 metres. The sinkin was effected by compressed air, and as the working con tained firedamp safety explosives were employed. Th safety chamber was placed at the end of the cross gal lery. Recently, as a result of firing a number of shot in the mine, there was rapid and extensive liberation o carbonic acid, sufficient to fill the two shafts and th gallery. During the time the shots were being fired, th men were ordered to shut themselves up in the safet chamber. Five of them, who did not obey the order were suffocated by the gas and could not be saved, bu the others, who did take refuge in the chamber, remain ed safe and sound.

Such chambers are of value in all mines which are sub ject to sudden outbursts of irrespirable gases, and it may be presumed that, in consequence of this accident at Singles and of the report of the Government inspector, their employment will become more frequent in French mines.

The petroliferous areas of Newfoundland are at tracting much attention. A company, the Newfound land Oil (Parent) Development Syndicate, Limited, has been formed in London, Eng., to acquire and exploit claims aggregating 119,680 acres in extent. The Gov ernment of Newfoundland has more or less pledged itself to exempt such enterprises from payment of im port duties on all necessary plant, material, and ma chinery.

Within the last ten years considerable prospecting has been done in the Silurian schists on the northwest coast. At Parson's Pond oil was struck at 1,200 feet and at 2,160 feet. A considerable quantity was shipped to St. John's. Fuller details will be found in the Canadian Mining Journal for September 15, 1909.

The only available records of shipments of molyb denite from Canada date back to 1902 and 1903. In the former year Mr. John Webber, of Toronto, shipped 6,500 pounds of ore from the township of Laxton, Victoria County, Ont.; and in 1903 Mr. A. Chisholm shipped from Sheffield Township, Addington County, about 85 tons of ore.

PROGRAMME OF THE MINES BRANCH.

The work of the Mines Branch of the Department of Mines for the ensuing season has been arranged as follows:—

The fuel testing plant in Ottawa is to be operated, under the direction of Mr. B. F. Haanel, for the purpose of experimentation and demonstration. A second producer, suitable for lignite and bituminous coal, is to be installed at the plant.

The Government peat bog at Alfred is to be operated for a period of about three months to demonstrate the latest process of manufacturing air dried peat. Several thousand tons will be produced during the present season. Part of the peat fuel produced will be shipped to Ottawa for use in the peat-gas producer plant now installed, and part will be sold in the neighbourhood for domestic use. The operation of the plant at the bog, which is open to public inspection, is under the direction of Mr. A. Anrep. The bog can easily be reached from Caledonia Springs, or from Alfred, on the Canadian Pacific Railway.

A cordial invitation is issued by the Mines Branch of the Department of Mines to all who are interested in the development of a peat fuel industry to visit the fuel testing plant in Ottawa, or the peat plant at Alfred.

The investigation of peat bogs in Canada, to ascertain their extent and to determine the quality and quantity of peat available, will be continued by Mr. A. Anrep, after the operating plant at Alfred is closed down for the season.

The iron ore deposits in the vicinity of Bathurst, N.B., will be investigated and additional magnetic surveys made by Mr. Einar Lindeman. Mr. Lindeman will also visit the magnetic sand areas on the north shore of the St. Lawrence.

The iron ore deposits of the Nictaux-Torbrook basin in Nova Scotia will be surveyed magnetically by Mr. Howells Frechette.

The investigation of the copper resources of Canada will be continued by Dr. A. W. G. Wilson. This season's work will be carried on in Ontario and in the Maritime Provinces.

Commercial processes for utilizing the sulphur content of pyrite ores are to be investigated with the object of preparing a special bulletin on the subject. Pyrite burning is of special importance at the present time with respect both to the sulphite pulp industry and to the preparation of mineral fertilizers. This work is to be undertaken by Dr. A. W. G. Wilson in the autumn.

The investigation of the molybdenum deposits of Canada will be continued by Dr. T. L. Walker for the purpose of completing and publishing a monograph on the subject.

A special report on the building and ornamental stones of Ontario is to be prepared by Dr. Wm. A. Parks. This report is to be the first of a series of monographs on the building materials of Canada.

A second edition of the monograph on mica for which there is a constant demand, is to be prepared by Mr. Hugh de Schmidt.

An ore dressing plant for experimental investigation into methods of concentrating certain iron ores, is to be installed at the testing plant in Ottawa by Mr. G. C. Mackenzie.

Plants where explosives are manufactured and stored in Canada are to be visited by Mr. Joseph G. S. Hudson.

An invitation has been issued through the Home Secretary of Great Britain to Captain A. P. H. Desborough, to visit Canada to consult with the Government with regard to the regulation of the manufacture and storage of explosives and with respect to the establishment of an explosive testing station.

Officers of the Division of Mineral Resources and Statistics will visit mining districts in various parts of the Dominion for the purpose of collecting statistics of mineral production and of securing information of general interest relating to the mining industry, including a record of new and recent developments, and data as to character of ores and products, prices, markets, and demand for various mineral products.

Mr. F. W. Harbord, London, England, is to investigate and report on recently invented processes in Europe for the production of spelter and zinc oxide.

Experts are to be engaged to investigate and experiment for the purpose of attempting to develop a process or processes for the utilization of the zinc ores of Canada in the production of zinc and zinc products in Canada.

A special expert is to be engaged to investigate metallurgical problems of economic importance. The plant of the School of Mines at Kingston has been placed at the service of the Mines Branch for this purpose.

NORTHERN QUEBEC.

The attention of prospectors is being drawn to the northern part of the Province of Quebec, adjacent to the Ontario boundary line. There are present, in this part of the province, important developments of Huronian rocks, such as those in which are found the large ore deposits of Ontario, and it is not unlikely that such finds as have been made in Cobalt, in Porcupine and in Larder Lake, may be duplicated on the Quebec side.

Realizing the importance of critically examining and mapping such areas, the Bureau of Mines of the Province of Quebec is sending a party into the country to the east of Lake Temiskaming, to map out, in great geological detail, parts of the Townships of Fabre, Duhamel and Laverlochêre. At the same time a careful examination will be made of all the workings, prospects and discoveries which have been made in the region. It is the intention to publish maps on a large scale, of one-half and one-quarter mile to the inch, which will be sufficient to show accurately the outline and the outcrops of the rocks. These maps will accompany a report which will have special bearing on the mining economies of the region.

Mr. Robert Harvie will be in charge of the party. Mr. Harvie is a mining geologist who has had several years' experience in the field, and whose training specially fits him for the work with which he has been entrusted. He is a graduate of McGill University and is at present instructor in mineralogy at Harvard University.

The rate of the growth of pig iron production in various leading countries is astounding. In the last forty years Great Britain's annual production has seen an increase of 66 per cent.; that of France has grown 147 per cent.; while the industries of Germany and of the United States have increased 740 per cent. and 830 per cent. respectively. In 1869 the order of producers was: Great Britain, United States, Germany, France.

To-day Great Britain has slipped to third place, and the present order is: United States, Germany, Great Britain, France.

Not less than 80 per cent. of the fluorspar produced is consumed in the manufacture of steel, chiefly in the basic open-hearth branch.

TOOL STEEL DIRECT FROM THE ORE IN AN ELECTRIC FURNACE.

By Alfred Stansfield, D.Sc., Montreal.

(Paper read before the Canadian Mining Institute, Annual Meeting, Toronto, 1910.)

At the Eighth Annual General Meeting of this Institute, which was held in Quebec in 1906, Mr. J. W. Evans, then of Deseronto, gave an interesting account of some laboratory experiments which he had carried out during the previous two years on the production of tool steel directly from the ore in the electric furnace.[1]

Mr. Evans had been obliged to construct with his own hands the 1 1-2 kw. electric generator he used for these experiments—thus proving his ability and determination—while he demonstrated his audacity by basing a large electric furnace industry, in the Provinces of Ontario and Quebec, upon the results of his laboratory tests in which one ounce of ore was smelted at a time to yield a button of steel.

The experiments made at that time showed (1) that from a sulphurous ore, containing 1 per cent. of sulphur, low carbon steels could be obtained having 0.05 per cent. to 0.07 per cent. of carbon and 0.08 per cent. to 0.17 per cent. of sulphur, and (2) that from a titaniferous ore containing 45 per cent. of iron and 7.6 per cent. of titanium a steel could be obtained with less than 1 per cent. of carbon and with the titanium varying from 0 to 1 per cent. The whole of the titanium could readily be removed by using enough lime in the charge, but it was desired to retain some titanium in the steel, on account of its valuable properties, and this could be done by using less lime. Lowering the amount of lime in the charge had, however, the attendant result of causing more silicon to enter the metal; the silicon ranging from 0.05 per cent. to 2.31 per cent. in the steel obtained. Some samples of electric furnace tool steel were shown which had proved satisfactory in small machine tools; they contained one-half per cent. of titanium.

The writer, at the next meeting of the Institute, criticised these experiments on the ground that so small an amount of metal might be more perfectly refined than would be possible in a larger furnace working more continuously, and showed this to be the case, experimentally, in regard to the removal of sulphur from sulphurous ores.[2]

Since the date of his paper, Mr. Evans has been enlarging his electric furnace plant and has directed his experiments mainly to the production of tool steel from magnetite ores containing titanium and traces of vanadium. The writer had the opportunity last summer of inspecting Mr. Evans' plant and assisting in his smelting operations, and considered that an account of these might be of interest to the members of the Institute, although, owing chiefly to Mr. Evans' ill-health, the data now available are by no means as full as could be desired, and this communication can only be regarded as a preliminary note.

Mr. Evans' plant, last September, consisted of a small cylindrical furnace about 18 inches high and 14 inches in diameter, having a pair of lateral electrodes and supplied with electric current at 110 volts from a transformer of about 20 kilowatts capacity. A rheostat was used to regulate the current, and it was necessary to keep the latter below 200 amperes. In general, it was only possible to utilize some 6 or 8 kilowatts in the furnace.

Figure 1 is a section of the furnace and shows the original brick lining, B, eroded by the action of the slag in the furnace, and a lining, L, rammed into the cavity before each operation of the furnace. M is the melted steel in the furnace, S the slag and C the partly reduced but unmelted charge of ore, charcoal and limestone. The electrodes, E, are 1 inch square graphite rods provided with holders for supplying the current and capable of being inclined more or less during the operation of the furnace. The openings through which the electrodes entered were closed as far as possible with an asbestos mixture, and a couple of bricks served as a cover for the furnace.

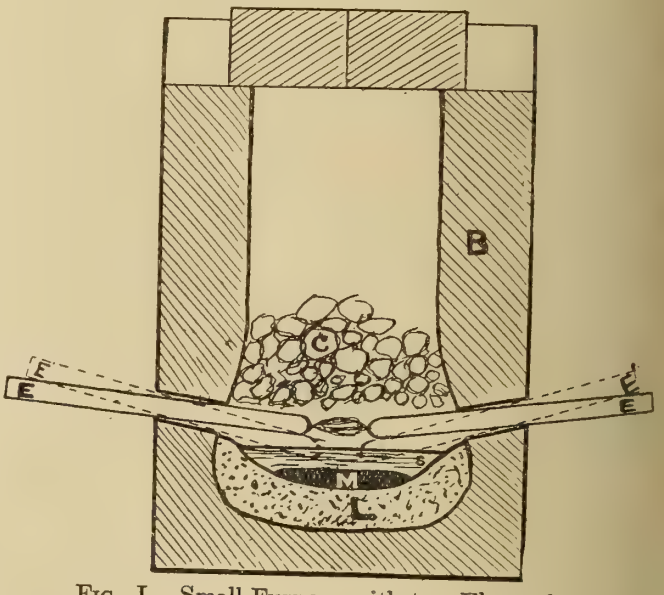


FIG. I. Small Furnace with two Electrodes.

The peculiar feature of the smelting practice in this furnace consists in the way in which the electrodes are manipulated. In the early part of each smelting run an arc is established between them, as in the Stassano furnace, and the heat of the arc is utilized for reducing the iron ore to metal and melting the metal and slag. The electrodes are shown in this position at EE. When the slag has filled up the furnace so as to immerse the ends of the electrodes, or by purposely depressing the electrodes, as shown at E, E, the arc is stopped and the current flows from one electrode to the other through the molten slag and metal. Mr. Evans found the latter method of heating to be more satisfactory and considered it essential for the refining of the steel.

The behaviour of the furnace was somewhat peculiar in this particular:—When running with the arc between the electrodes EE, the resistance was very low, so that the electrodes had to be drawn widely apart and even then a current of 200 amperes was produced with a voltage of only 30 or 40. Immediately the electrodes were dipped into the slag at E, E, and the arc broken, the resistance was increased so that 60 volts only produced a current of 100 amperes or less. This condition was unstable, and there was always the possibility of an arc

forming between the electrodes above the slag, and this would immediately cause a great increase in the current. As the immersion of the electrodes in the slag led to a heavy loss of electrodes, the attempt was made to keep them just above the slag and to maintain a short arc between each electrode and the molten slag. Owing to the high resistance of the slag, this was found to be impossible, but a later type of furnace has been found to work very satisfactorily in this way.

The ore treated was a magnetite from the Orton mine in Hastings County, Ontario, and contained:—

Iron	51.45 per cent.
Sulphur	trace
Titanium	7.50 per cent.
Nickel	0.12 per cent.
Vanadium	trace

For smelting on a small scale it was found desirable to crush the ore, the charcoal used to reduce it and the limestone used as flux. These powders were mixed together, briquetted with the aid of molasses and water and baked before smelting, a typical charge being:—

Ore	100 ounces.
Limestone	20 ounces.
Charcoal	18 ounces.
Molasses	10 ounces.
Water	16 ounces.

Starting with a hot furnace and using between 5 and 6 kilowatts, the operation would be completed within the hour and would produce about 3 pounds of steel.

The steel was tapped from the furnace without any addition of ferro manganese or other deoxidizer and always gave a perfectly sound and tough ingot. Mr. Evans has obtained in this way many ingots of steel, which have proved to be a very good quality of tool steel. Unfortunately at the time of the writer's visit the lining material had become contaminated with a little plaster of Paris, and, in consequence, the steel was found to contain over 0.10 per cent. of sulphur, which impaired its forging quality, though it made good tools. The presence of sulphur in the furnace lining was not discovered until it was too late to obtain a fresh supply. One sample of steel, from which good lathe tools were made, contained:—

Carbon	1.25 p.c.	Phosphorus	0.051 p.c.
Silicon	1.06 p.c.	Titanium	Nil
Sulphur	0.124 p.c.	Vanadium	Nil

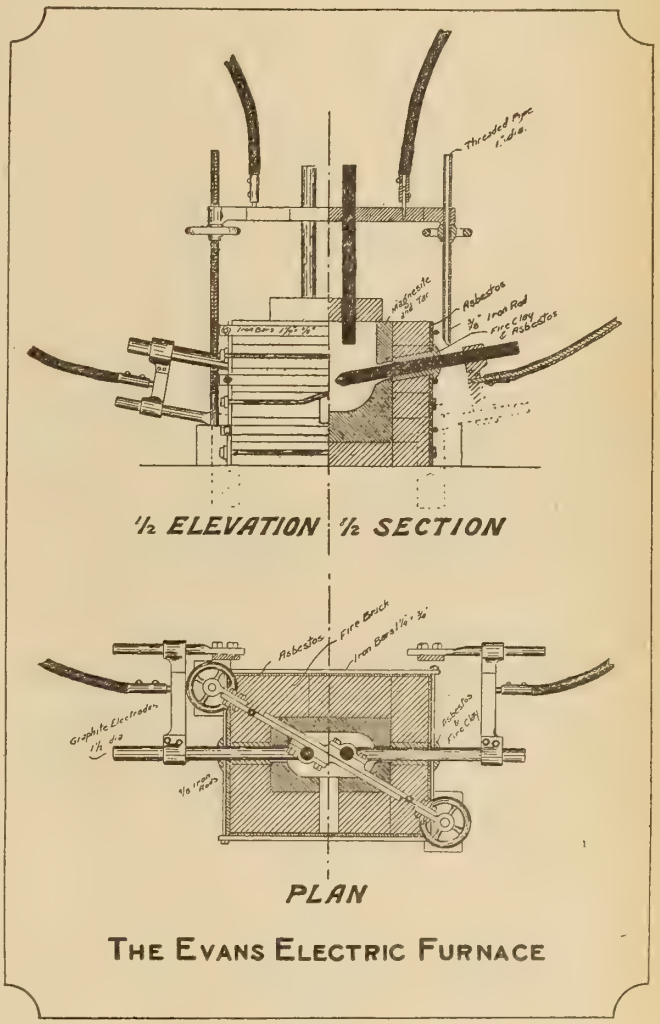
Mr. Evans has found that the steel produced by the direct reduction of this titaniferous magnetite in the electric furnace has peculiarly valuable qualities as a tool steel. He attributes these to the titanium and perhaps also to the nickel and vanadium in the ore. Non-titaniferous magnetites, from the Rankin mine, did not yield sound steel when smelted in Mr. Evans' electric furnace.

He has submitted samples of his steel to various steel experts, obtaining very satisfactory reports, and a piece of his steel made into a lathe tool and tested at McGill was found to be decidedly better than the Firth tool steel. The tool was tested just as received from Mr. Evans. It was ground when necessary but not retempered. The tools were usually cut from the ingots—not forged—but a knife has been forged from some of this steel.

In connection with these facts it should be noted that in operating a small furnace it is not practicable to take a sample of the steel from the furnace and make a quick chemical test of it, as would be done with a larger furnace, and that, in consequence, the composition of the steel could not be adjusted in the furnace and the analysis of the resulting steel will not in general be as good as it could easily be made when working on a larger scale. It should also be noted that no ferro-manganese or other additions have been made to any of the steel obtained up to the present. It is, therefore, quite likely that when working on a larger scale, steel can be produced of even better quality than has so far been obtained, and it is certain that the steel can be obtained of practically constant composition.

At the meeting, a number of tools were shown which had been made from steel produced in the Evans furnace. Several of these tools were made from a bar of steel which analyzed:—

Carbon	0.91 p.c.	Titanium	trace
Sulphur	Nil	Vanadium	Nil



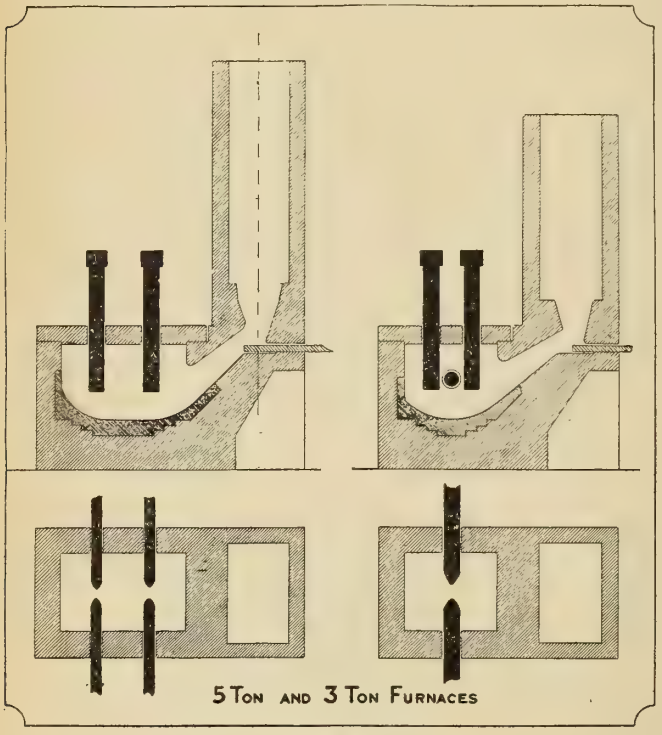


FIG. II.

Mr. Evans has quite an extensive workshop in which he constructs his furnaces, crushes the ore and fluxes, and tests the steel he obtains. Views of this are given in the accompanying photographs.

If it is admitted that a good tool steel can be made directly from the ore in the electric furnace, the most important remaining question is whether the cost of the process will be low enough to render it commercially practicable. With this object in view the writer made careful observations of the consumption of charcoal, limestone, electrical energy and electrodes in Mr. Evans' experiments, and the results of these observations may be stated as follows:—

1 lb. of tool steel reduced in the small electric furnace required
2.1 lbs of magnetite ore from the Orton mine.
0.4 lbs. of limestone.
0.4 lbs. of charcoal (including carbon in binding material).
0.08 lbs. of electrodes (Acheson graphite electrodes at 12c. a lb.).
3.0 kilowatt hours.

Most of these figures could undoubtedly be reduced in the case of a larger furnace, and it will be safe to state that a furnace making one ton or upwards of steel in 24 hours would not require more than 0.35 lbs. of charcoal and 2 kilowatt hours per pound of steel, while the electrode losses could certainly be reduced to not more than half the above figure, or say 0.03 pounds per pound of steel. Taking the electrical horse-power year at $20, the cost of 2 kilowatt hours would be 0.62 cents, and the electrodes would cost 0.36 cents, or a total cost for ore, charcoal, limestone, electric power and electrodes of

Figs. III and IV.

about 2 cents per pound of steel. The electrode losses in the test runs were greatly increased by the practice of allowing the ends of the electrodes to dip into the slag in the furnace. If, as is the case in the larger furnaces, the electrodes do not enter the slag, but are merely employed for producing an arc, the losses should be very much less. The rate of loss must also be proportional, more or less, to the surface of the electrode, and as the surface of the electrode, or at least the hottest part of the electrode, becomes proportionately less in larger furnaces, there is no doubt that a decided improvement will be shown in this particular.

Independent information with regard to the cost of running such a furnace on a somewhat larger scale can be obtained from the published test of the Stassano furnace in Italy made by Dr. Goldschmidt, in 1903.[3] The test was made on quite a small furnace of about 80 kilowatts, turning out 70 pounds of mild steel in two hours, smelted directly from pure hematite ores. One pound of steel required:—

1.63 lb. hematite ore.
0.20 lb. limestone.
0.26 lb. charcoal.
0.20 lb. carbonaceous additions.
0.012 lb. electrodes.
1.44 kilowatt hours.

These figures confirm what has been stated above with regard to the probable cost of the Evans process on a working scale and show that even better results may be expected.

The cost of labour, management, etc., will vary so much with the locality and particularly with the scale on which the plant is constructed that it does not seem worth while to attempt to estimate them. It may be mentioned, however, that Dr. Goldschmidt, in the report already referred to, states that in a plant of 5,000 h.p., located in Italy, producing 30 tons of steel in 24 hours, from rich hematite ores, the total cost of the steel, including ore, power, electrodes, labour, maintenance, etc., but not apparently interest or depreciation, would be very close to 1 cent per pound.

In connection with the above figures it should not be forgotten that the best tool steel is not rolled from the ingot but is drawn down under the hammer to obtain the finished bar. The cost of this process would have to be considered in determining the cost of production of the steel bars.

In Mr. Evans' experimental furnace only two electrodes were employed, and these could be placed nearly horizontal, or could be inclined at an angle in order to enter the slag. On the large scale it is intended to attain the same results by having two pairs of electrodes; one pair being vertical and the other nearly horizontal. This arrangement, which is shown in figures 2, 3 and 4, enables the horizontal electrodes to be used, as in the Stassano furnace, for the purpose of melting the charge, while the vertical electrodes can then be substituted and used as in the Heroult furnace for heating the molten charge during the finishing stages of the process.

Figures 2 and 3 show furnaces of this kind which Mr. Evans has constructed. The lateral electrodes are slightly inclined so that the arc may be near the charge while the openings through which the electrodes enter may be well above the slag level. The vertical electrodes pass through the roof of the furnace, and their holders are insulated from each other but are bolted together for greater strength. In this way the two electrodes are regulated together. In these furnaces it is necessary to withdraw the lateral electrodes before the vertical pair can be lowered into position, but in a larger furnace the electrodes could be placed so as not to interfere with each other, as in the right hand drawing in Figure 4.

With the furnaces shown in Figures 1, 2 and 3, the ore is introduced directly into the body of the furnace, as is also the case with the Stassano furnace. In the latest designs, see Figure 4, Mr. Evans is adopting a suggestion of the writer and adding a tower, in which the ore is heated, and partly reduced before it enters the electric furnace itself, and this modification should effect a considerable saving of electrical energy and even of charcoal and electrodes.

When promising this paper for the Toronto meeting, the writer expected to be able to make further tests with Mr. Evans' furnace in order to obtain more exact data for the cost of operation, and to have a supply of steel for a full set of chemical and mechanical tests. Mr. Evans' unfortunate illness prevented these tests and the writer was therefore unable to present as complete an

account as he would have liked of this interesting process.

Mr. Evans has acquired the Orton iron mine, in Hastings County, and informs the writer that more than 2,000,000 tons of titaniferous iron ore has been proved there by the diamond drill. The core shows the ore body to be 60 feet wide at 280 feet below the surface. The last analysis of the ore gave:—
60.84 p.c. iron, 7.5 p.c. titanium, 0.11 p.c. vanadium.
There is a quantity of limestone on the property, an abundance of wood for charcoal, and power can be brought from Campbellford at a reasonable figure.

The process of making steel in the electric furnace from titaniferous magnetites, which was inaugurated on such a small scale four years ago, should prove of great value in Canada, where these ores, charcoal and water power are all available, and where tool steel is at present imported.

PERSONAL AND GENERAL.

Mr. J. B. Tyrrell has returned from a professional visit to Quebec.

Mr. Martin Nordegg leaves for Alberta and British Columbia on June 30th.

Mr. J. B. Tyrrell has been elected a fellow of the Royal Society of Canada.

Mr. T. J. Vaughan-Rhys has assumed management of the Portland Wonder mine.

Mr. H. P. Davis passed through Toronto on his way to New York, on Friday, June 10th.

Mr. Frederic Keffer, of Greenwood, B.C., was in Colorado, U.S.A., during the early part of May.

Dr. J. Bonsall Porter, of McGill University, will shortly leave Montreal on a visit to Europe.

Mr. Fred. Pearson, of Halifax, N.S., is in Venezuela arranging to obtain control of large iron deposits.

Mr. W. S. Lecky has been elected an associate member of the Institution of Mining and Metallurgy.

Mr. W. M. Brewer, of Victoria, B.C., recently went north on one of his periodical visits to southeast Alaska.

Mr. Alexander H. Smith, consulting engineer for Porcupine Goldfields, Limited, has returned to Porcupine after a brief visit to Toronto.

Mr. O. N. Scott, general manager of the Cobalt Provincial Mine, was in Toronto recently. Mr. Scott reports most satisfactory progress.

Major, the Hon. J. E. P. Vereker, Kenora, has returned from a trip to Gold Rock. He reports considerable mining activity in the Manitou region.

Mr. Charles Levick, representing Swift, Levick & Company, Sheffield, Eng., passed through Toronto during May on an extended business tour through Canada.

Mr. A. T. Graham, formerly connected with the Red Cliff (Portland Canal) mine, has been placed in charge of the MacDonald-Pearson and Lydden-Bunting groups on Glacier Creek.

Mr. A. G. Larson, superintendent of the Le Roi mine at Rossland, B.C., was lately at the Ikeda Bay mine, Moresby Island, of the Queen Charlotte group, in the capacity of consulting engineer.

Mr. Lawrence Adams, late vice-president and general manager of the Guanajuato Amalgamated, is leaving for Montana and California in connection with mining properties in which he is interested.

The Hon. Mr. Templeman and Mr. R. W. Brock, Director of the Geological Survey, have returned to Ottawa from New York, Washington and Philadelphia, at which cities they inspected various museums.

Mr. W. Murdoch Wiley, of New York City, accompanied by Mr. R. B. Lamb, mining engineer, of 15 Broad Street, New York City, has left for Montana to examine the Ohio-Keating mine. They will also make mine investigations in Idaho and California."

Mr. W. Anderson, civil and mining engineer, of Vancouver, has gone to Peru to report upon a hydro-electric power scheme for the Cerro de Pasco Mining Company, of which Mr. A. B. W. Hodges, late of the Granby Company, is general manager.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay.—The Dominion Coal Company's output for May will be approximately 297,000 tons, comparing with 316,000 tons in May of last year. The output for 1910 to the end of May is 1,195,000 tons, against 1,273,000 tons in 1909, so that the difference between the two periods amounts to only about 78,000 tons in favour of last year. The Lingan collieries have put out a fairly large amount of coal during May, amounting to over 13,000 tons. No. 12 colliery is now producing over 500 tons daily, and on several occasions has almost reached 600 tons. The output for June will probably be about 340,000 tons. In June, 1909, the output was 355,000 tons, but it is hardly likely that this figure will be reached, as last year the men were working steadily, expecting the coming strike.

The Sydney & Louisburg Railway, which up till recently was owned by the Dominion Coal Company and operated as a part of their works, has been incorporated under its own charter as a separate corporation. Some modifications of the hitherto established routine of this railway will no doubt take place under the rearrangement.

The Whitehaven Disaster.

The catastrophe at Whitehaven has an especial interest for Cape Breton readers, because the conditions under which coal-mining is conducted at the Wellington Colliery are similar to those under which much of our Cape Breton coal will have to be won. The colliery stands close to the edge of the cliff, and the workings extend to a distance of five miles out under the sea. About three and a half miles out, there is a large friction haulage plant actuated by an endless rope from the shaft. The main haulage transmission shaft serves five ropes, which branch out along as many roads extending into the further workings. The origin of the disaster is not fully cleared up. It is supposed to have arisen through an explosion in one of the branch haulage roads beyond the main friction gear, but the fate of the entombed men appears to have been sealed by a fire at this point which was fed by the wood around the haulage gear and the dust and oil that naturally accumulated in such a place. Two men only managed to get past the friction gear, and all the remaining men, 130 in number, must have been quickly suffocated by the fumes from the burning wood and oil. A desparate fight was made to subdue the flames, but after progressing

some 140 yards and getting within 80 yards of the supposed seat of the fire, the rescue parties were driven back. An hour before midnight two men from the Mining Engineering Company of Sheffield, equipped with "Shamrock" apparatus, descended the mine, but were only able to get within 130 yards of the fire, when they had to beat a hurried retreat. Their helmets and cylinders were too hot to touch. Such courage is magnificent, but there is no due advantage to be gained by sending men into such danger. Rescue apparatus has many possibilities, but it will not aid men to do the impossible. Other rescue parties afterwards arrived from Normanton and Hanley, but they could do nothing, and the intake was bricked up. Many indignant protests were made against the management for their action in sealing off the burning section and the entombed men, but all those competent to judge express the opinion that nothing else could be done. Whitehaven is six hours' journey from Sheffield, and the Mining Engineering Company's men started within two hours from the time they received news of the fire. From the short account contained in the letter received by your correspondent it cannot be stated that the rescue apparatus would have been of more avail had it been immediately on the spot, as owing to the fire being so far "in-bye" it appears to have gathered violence unnoticed by those on the intake side of the friction gear. Certain it is, however, that it would not have been any more difficult for the rescue parties had apparatus been available at the commencement of the fight, as without such protection they fought the fire for hours before being compelled to leave the entombed men to their fate. This disaster again emphasizes a point which has often been made in the JOURNAL, namely, that if oxygen rescue apparatus is to be of any use in mine disasters, it should be treated as an auxiliary to the underground fire brigade, should be immediately available, with a sufficient number of trained men to make effective use of it, and to relieve one another rapidly. Two men, with all the courage and skill in the world, are impotent in face of a mine fire that has had time to gather strength. In planning the extensive haulage ways which some day will convey the submarine coal which lies off the shores of Cape Breton this disaster should be borne in mind. It would seem that the entire avoidance of inflammable material in the construction of the elaborate haulage plants which will be necessary would be advisable, and the substitution of concrete for wood should be enforced strictly.

After the foregoing had been written the "Colliery Guardian" of the 19th May came to hand, containing an editorial article on the Whitehaven fire. The conclusions reached by this authoritative journal, with access to more exact sources of information than those possessed by your correspondent, are so strikingly corroborative that it will be well to quote them. Speaking of the hostility aroused by the decision of the management to brick up the intake, the "Guardian" remarks: "The real test of moral bravery on such occasions is to know when to desist from futile attempts to rescue; whenever a colliery explosion occurs there is always a multitude of willing volunteers ready to run the greatest hazards, but it requires bravery of a higher order to close the shafts against them." In connection with the magnificent bravery shown by Thorne and Littlewood, the Mining Engineering Company's men, and the usefulness of rescue apparatus in such cases, the article goes on to say: "From the details, however, that are before us at this stage it is a reasonable conclusion to form that had breathing appliances been on the spot at the time of the explosion instead of thirty hours later, lives might have been saved; the chief justification for this belief exists in the fact that two men, after persistent efforts, managed to traverse the fire area from the workings, and left beyond several workmen who were then in full possession of their faculties. The moral is that, to be of service, there must be a rescue station within easy reach of, and trained men at, each colliery. One of the few happy results of the Whitehaven disaster may be to convert colliery owners to this view, not only in Cumberland, but in some other districts."

There is not as yet a single breathing appliance on the mainland of Nova Scotia. Surely there is no need to point a further moral.

The Barometer and Mine Explosions.

Commenting on the recent disastrous mine explosion at Whitehaven, England, elsewhere referred to in this letter, the "Montreal Gazette" touched upon the statement that was given considerable currency by the cabled newspaper reports that the explosion was coincident with a high barometer, the approach of which had been predicted in the newspapers by what in known as a "colliery warning." The "Gazette" expressed the opinion that in the future the colliery manager would pay "the same careful attention to his colliery manager would pay "the same careful attention to his barometer as the master of a vessel does to his compass." The comment is a little *naive*, as under the Coal Mines Regulation Act in England, every coal mine must be provided with two barometers, one at the mouth and the other at the foot of the shaft. The reading must be daily taken and recorded by a responsible official—usually the underground manager. The "Gazette" is, however, not wholly to be blamed for the importance it attaches to the "colliery warning," for many people even in England itself are not aware that the "warning" is not an official announcement. The "Colliery Guardian" of London recently poked fun at the expense of these solemn "warnings." They have appeared regularly in all the English newspapers for some years past, and forecast an approaching change in the atmospheric pressure which will cause disturbance in the equilibrium of the mine gases. Where large wastes or "goafs" exist it is well known that a change in the barometric pressure may force out accumulations of dangerous gases into the workings, or conversely a diminution of the pressure may liberate gases which are confined in cavities, but bodies of gas of this nature are much more sensitive to changes in atmospheric pressure than any barometer ever invented. The result of a change of pressure will be felt in the mine long before any published "warning" can be given circulation. The "colliery warning" which appears in the newspapers is generally read long after the atmospheric change has passed and gone, and in mining circles these announcements are regarded as an elaborate joke. The Meteorological Bureau disclaims all knowledge of these "warnings," and the Government know nothing about them, so that their origin, like the birth of Jeames, "is wropt in mystery."

ONTARIO.

Cobalt.—At the Hudson Bay a new vein has been discovered on the 100 foot level, to the south of the shaft. It is about an inch and a half wide and carries high values in silver.

Another important ore shoot has been located on the Lawson property, on the No. 11 vein. From the shaft a drift was run on the vein at a depth of 50 feet, and high grade ore was encountered. Some work was done from the 75 foot level, but at that depth the values in the vein were low. Now that the property is no longer handicapped for lack of power, work will be carried on much more rapidly, and all the veins will be opened up.

Several engineers for the Dominion Government are in the district, making examinations of the different lakes and rivers, with a view to conserving the great bodies of water that are wasted every spring. Practically all this section drains into the Ottawa River, and in the spring the water is much higher than is necessary, while in the fall the water gets so low as to prove a serious handicap. On account of the heavy snow-fall the lakes and rivers rise to great heights after the break-up. Lake Temiskaming, the largest body of water in the district, usually rises about fourteen feet, and every spring this great supply goes to waste. It is the intention of the Government to build a series of dams, at the points where they will hold back the greatest amounts, and by letting out the water as it is needed, thus regulate the flow in the lower Ottawa. Some of these dams are now under construction, and work will be commenced on others in the near future. The possibilities for the generation of power that these dams will afford are practically un-

limited, and although they will not likely be used for some time on account of the small market, due to the sparsely settled conditions of the country, they will always be a vast reservoir for future needs.

A new vein carrying high-grade ore has been found on the Nova Scotia property. The ore body, which was opened up by underground exploration, varies in width up to five inches, and consists of calcite and native silver. Now that the difficulties between the Peterson Lake and this company have been settled, the Peterson Lake lease is being worked again. The new mill is in operation, but has been working such a short time that it is impossible to state how the process will turn out. The ore is treated by straight cyanidation, which is a decided departure from the majority of plants in the district.

The Standard Cobalt Mines, which is the operating company of the Cobalt Central, is in the hands of a receiver, with liabilities amounting to about $50,000. The company controls over 700 acres of ground, only a small portion of which, however, has been prospected. The mine and mill are on the Big Pete claim on Diabase Mountain, and although the ground has not been very well developed, several good veins have been found. As a general thing the ore is found in small stringers over a width of about eighteen feet, but on the fourth level there is one vein showing in the bottom of the drift that will average about three inches in width, and that can be traced for several hundred feet. The mill has a capacity of 100 tons a day, and there are several months' supply of mill rock broken in the mine. The mill also treats considerable custom ores from the surrounding mines. During the last few months a sharp fight for control has been waged by a minority interest among the shareholders, headed by J. S. Bradley, a New York broker. In the meantime the financial affairs of the company steadily grew worse, although the property made more or less regular shipments of ore to the smelter.

After many delays and disappointments, the Cobalt Hydraulic Company has at last started the big plant at Ragged Chutes, and as a consequence a good many more mines have shut down their compressors and are operating with the new power. The pressure at the mines is about 120 pounds, but the reducing valves cut this to about 100 pounds. After the water was turned into the shafts, but before the air was allowed into the pipes, the automatic blow-off that operates through the tail shaft, formed a regular geyser hundreds of feet high that was one of the most remarkable sights ever seen in this country. This plant is the largest natural air compressor in the world and has an estimated capacity of about 5,000 horse-power. The air is transmitted from the plant through nine miles of twenty-inch pipe. From the end of this line a twelve-inch loop encircles the camp, and the air is drawn off in smaller pipes to the various mines. One great advantage of this air is its remarkable freedom from moisture, due to being compressed at a constant low temperature. Since consumers have started using it, however, it has developed that the miners find some difficulty in keeping candles alight, and the effects of dynamite smoke after blasting are also said to be more serious than formerly. The inventor claims that this is due to the oxygen being absorbed by the asphalt with which the pipes are coated, and that this feature will shortly disappear. The Mines Power Company is now running steadily, supplying air and electricity, and will shortly have the fourth compressor in the Brady Lake sub-station in operation. This will give practically one spare compressor in case of an accident happening to any of the four. The three at present installed handle the load easily, but without having very much to spare. The Cobalt Power Company will shortly have all its generators installed, and will then have no difficulty in handling the load. With these three companies operating, Cobalt will be in a very enviable position with regard to power, as the supply is ample and the price is very low compared with the previous cost when generated by steam. On the face of it, the supply seems much greater than the demand, and it is not outside the bounds of possibility that an amalgamation of some sort may take place in the future.

At the Temiskaming Mine a new vein of exceptionally high grade ore has been discovered on the 400 foot level. No. 2 vein on this level is also making good ore, the vein being in some places eight inches wide of ore that will run about 4,000 ounces to the ton. The mill is handling up to 100 tons a day and is stated to be producing about $1,000 worth of concentrates every twenty-four hours. From the time it commenced operating until the end of May the mill treated 2,218 tons of ore, having an average assay of 33 ounces, and produced 59,400 ounces of silver. The main shaft is being sunk to a depth of 500 feet, and when this level is reached it will be the deepest working in the camp.

Surface prospecting on the Nipissing property has already this season yielded excellent results, and five new veins carrying high grade ore have already been found. Three of these varying in width from one to two inches and running parallel about thirty feet apart, were discovered in the vicinity of No. 49 shaft. These will be opened up from tunnel No. 28, the end of which is between two and three hundred feet away. The last discovery was made in the Keewatin area in the vicinity of Cart Lake, where som geood silver was found. This territory had been partly prospected before, but a more careful examination of the ground resulted in the discovery. This company is finding that running the trenches 100 feet apart is not working close enough, and now the ground is being cut up with trenches about fifty feet distant from one another. The management is convinced, however, that even with this careful method of doing the work many veins escape their notice. As a consequence they will experiment with washing off all the overburden on some portions of the property. A couple of large pumps are now being installed, and it is expected will be operating shortly. The disposal of the tailings will present serious difficulties, but it is believed that the ground will be worked in sections, and that when one part has been washed and thoroughly examined the overburden from the ground above will be washed down on it. This method will make absolutely certain that no veins showing on the surface escape notice. The cost will be high and the work will take a long time, but the results will undoubtedly be large.

It is stated that the production of the Buffalo for their fiscal year amounted approximately to 1,500,000 ounces. The reserves have been considerably augmented by the extension of the territory to the west, where it was not expected to find ore. In drifting on the vein to the west, a roll in the underlying Keewatin was cut, and the values gave out entirely. Some time afterwards work was again started in the drift, which shortly passed into the conglomerate. With the change of formation the values came back as high as formerly, and now the drift has been pushed several hundred feet more and the heading is still in good ore. It is understood that the cyanide plant is not as great a commercial success as it was expected to be, and that it may be shut down before long. Results from the concentrating plant are, however, very satisfactory, and it is thought that if a little closer saving were made on the slime-tables the cyanide plant could be done away with.

Another high grade vein has been struck on the Cobalt Provincial, which was formerly owned by the Government. The discovery was made in the bottom of the new shaft, where there is from four to five inches of ore carrying high values in silver. This was at a depth of 120 feet and is believed to be a different vein than the one cut at a depth of 80 feet in the shaft.

The opening up of the third level of the Coniagas is giving much better results than was anticipated by the management. Work is now being carried on at a depth of 225 feet, and a few days ago the cross-cut opened up the No. 2 vein. It is considerably wider and more consistent than on the second level, and the values are fully as high. This is the first of the known veins to be located on the third level, but it is expected that the No. 6 vein will be cut in a few days. The management has been prevented from running the new addition of thirty stamps on account of an insufficient supply of water. A new pump is being installed, however, and this defect will be remedied very shortly.

The new plant for sampling the high and low grade ores of Cobalt is now practically completed and will be receiving consign-

ments in a few days. All the ore when it is received is crushed in a ball mill, and from the fines four separate and distinct samples are taken. This ensures a thorough check on the assays. The metallics from the ball mill are melted down separately and the resulting product shipped as fine silver bullion. One of the great advantages of the plant will be the possibilities it offers to grade the values of the ores to meet the requirements of the smelters. Several of the smelters pay a certain percentage of the silver contents, depending on the assay of the ore, and this usually varies one-half of one per cent. for each five hundred or thousand ounces to the ton. The sampler has several storage bins where the ore may be held in order to change the grade if required. Arrangements have also been made with some of the smelters to accept the sample as taken at the Cobalt plant, and this will do away with the necessity of having a representative at the point where the ore is treated.

Diamond drilling on the Foster property has resulted in the discovery of a vein carrying values at a depth of 400 feet. It is not known how high the returns from the assays were, but they were encouraging enough to determine on further exploratory work with a shot drill. This drill has been ordered and will be here almost any time.

The management of the cobalt smelter at Copper Cliff has decided to increase the capacity of the plant to 800 tons a month. This was the first smelter in Canada to treat Cobalt ores, and for the year 1909 they treated practically half of the high grade output of the camp. From the time it started in 1905 till the end of 1909 it treated 13,616 tons of ore and produced 22,633,430 ounces of silver. They also produce refined arsenic, but the shipper receives no payment for this. The cobalt and nickel are collected in the form of a speiss, which also contains considerable silver, and this is sent to the States for treatment. The company also intends to put up a silver refinery, and when this is completed they will be able to pay for the ores in a much shorter time than is now possible. At the Deloro smelter an oxide plant has been built that treats the speiss and produces commercial cobalt oxide and recovers practically all the values in the ores. As the supply of cobalt has been steadily increasing the last few years, this company has been carrying on some interesting experiments, with a view to extending the uses to which it is put and thus increasing the demand. One result of these experiments has been the production of several pigments in different colours. This plant also produces refined white arsenic.

Since the advent of the new power a decided improvement has taken place in the Savage property. No. 4 vein has been cut in a cross-cut from No. 3 vein and shows a good width of high grade ore. Before this the ore reserves on the property were estimated at three-quarters of a million ounces, and if this vein proves up well on the lower level they will be considerably increased. The shaft is to be sunk another 75 feet and a new level opened up. At the present time the stopes and drifts are full of ore, but with the small sorting plant in operation this will soon be cleared up and underground development can proceed. New camp buildings are also to be erected.

BRITISH COLUMBIA.

As the spring advances there is much activity in the mining districts, especially in those in which little can be done during the winter. With the melting of the snow prospectors are busy again, and numbers of them are already afield, preparing to take full advantage of the whole time in which prospecting can be done to advantage. There has been quite a rush of men to the North—to Queen Charlotte Islands, the Skeena country, and especially to the Portland Canal district. Much excitement has prevailed in the British Columbia coast cities relative to reported finds of high-grade ore on several mineral claims in the vicinity of Portland Canal, and much is expected from that district. As yet, though, substantial development work has been restricted to only a few properties, so that the question of tonnage of ore available has still to be dealt with. The prospects are generally regarded as most hopeful. Probably some of the so-called mining companies are mere promoting schemes, but there is no doubt several other organizations are genuine and their main object, bona fide mining.

Coal Mining Prospects Good.

The outlook for coal is more promising, perhaps, than for any other mineral being mined in the province. This applies to all the districts in which coal has been developed, and as well to several others in which coal measures believed to contain workable seams of coal have also been found. In Southeast Kootenay there are, beside the well-known and productive coal mines of the Crow's Nest Pass, Hosmer, and Corbin companies, respectively, large quantities of coal of excellent quality in the upper Elk River country, while other fields, though as yet not nearly so well prospected as those of the upper Elk, are known to occur in the Flathead and contiguous districts comprising the extreme southeastern part of the province. A six-foot seam of coal is being developed near Midway, in the Boundary district. In the Similkameen and Nicola Valley districts, now to some extent provided with railway transportation facilities, coal is being produced on a commercial scale, in small measure near Princeton, Similkameen, and to the extent of from 800 to 1,000 tons a day at Nicola Valley mines. One company has been formed to develop coal lands north of Kamloops, in a part of the country soon to be made accessible by the construction of the extension through British Columbia of the Canadian Northern Railway, which system is well established in the adjoining province of Alberta. In different parts of the very large area of country north and south of the route of the Grand Trunk Pacific Railway—in Northern Cariboo and in several widely-separated parts of the big Skeena country, coal has been found, and the construction of railways is being awaited to provide necessary transportation facilities so that coal may be mined and sent to whatever market shall be found for it. It is claimed by experienced coal prospectors that a large and productive field will be opened on Graham Island of the Queen Charlotte group, and if this be done the value of this fuel supply will be great, chiefly on account of the comparative nearness of the coal seams to tidewater, the good quality of the coal, and the convenience it will be to steamers engaged in the northern British Columbia and southeastern Alaska coast trade, which is yearly expanding and becoming of considerably increased importance. Then there are the newer developments on Vancouver and adjacent islands, some of which are already adding an appreciably large tonnage to the output of the British Columbia coast coal mines. Beside the big mines that have been productive for many years—the Western Fuel Company's and Dunsmuir collieries—there is the Pacific Coast Coal Company's South Wellington mine, now an established producer with a fairly large tonnage, and two or three small mines, with as yet but a small production. Then there are other coal properties being developed in the northern part of Vancouver Island, beside some on two or three of the smaller islands close by. The foregoing information is incomplete, but it will serve to indicate in a general way that there is ample warrant for the claim that the coal-mining industry of British Columbia is in a flourishing condition and that its expansion will be considerable in the near future.

In the Kootenay Districts.

It has been reported that the Consolidated Mining & Smelting Company of Canada, Limited, is negotiating for the purchase of the North Star mine, in Fort Steele mining division, East Kootenay. Years ago this mine was the most productive silver-lead property in British Columbia, but its output during recent years has not been large, although it has been operated at a profit. It is managed by Mr. Neil McL. Curran. The group contains six mineral claims and fractions, having a total area of about 300 acres, situated within two miles of Kimberley, the northern terminus of a branch of the C. P. R. Company's Crow's Nest line. The mine has been extensively developed and, according to the published report of one of the officials of the

Mines Branch of the Dominion Department of Mines, has produced a large tonnage of silver-lead ore, averaging, approximately, 30 ounces silver per ton, and 40 per cent. lead. The quantity shipped up to 1906, inclusive, was 69,500 tons. In 1907, the output was 3,094 tons, having an average lead content of 20 per cent., and of silver 15 ounces per ton. The 1908 returns are not now available to the writer, but in 1909, nearly 3,000 tons was shipped, this containing approximately 39,000 ounces of silver and 711,000 pounds lead. The bulk of the ore shipped contained an excess of iron in oxidized form, and very little sulphur, consequently, the smelting charge on it was low. Mining costs were stated several years ago as having been $2.33 per ton of ore mined. A former manager described the ore-bodies as being basins of ore, lying flat, and having a maximum thickness of about 70 feet. During recent years, though, the ore shoots mined have generally been small and disconnected. An important discovery of ore was reported a short time ago. The power equipment of the mine includes three 60 h.p. boilers, one large and two small hoists, a 5-drill air compressor, and a diamond drill. An aerial tramway, one mile in length, connects the mine with ore bunkers on the C. P. R. line near Kimberley.

The season in the Slocan mining camp has opened auspiciously, for there is much work in progress, more is to be undertaken, and the railway from Kaslo to Sandon will hereafter be operated right through, after having been closed beyond McGuigan for a comparatively long time. All the zinc concentrate made at the Whitewater mill during the winter has been shipped to the United States, the silver-lead product going to the Consolidated Company's works at Trail, B.C. Near the end of the cold weather season shortness of the water supply necessitated closing this mill for a few weeks, but it will soon be running again. Meanwhile, new ground has been explored in the Whitewater Deep mine, and a contract has been let for putting up an incline raise from the breast of the 2,000-foot adit tunnel driven last year, by the Deep Mine, Limited, from the railway level. When the raise shall be up, 150-foot cross-cuts, driven to prospect for ore before continuing to raise toward the old workings at about 500 feet above the deep-level adit. Zinc ore is again being shipped from the Lucky Jim mine, now that the weather is favourable for the railway company handling it without difficulty. The erection at Kaslo of a mill for concentrating the second-grade ore from the Lucky Jim is promised. Progress at the Rambler-Cariboo continues to be satisfactory and the outlook for a profitable year is promising. The annual general meeting of shareholders in the Rambler-Cariboo Mines, Limited, has been called for June 14th, at Kaslo. Byron N. White, managing director of the company owning the Slocan Star group, has gone to Sandon from Spokane, Washington. The operation of both mine and mill on a similar comparatively large scale to that in progress before the Star vs. White lateral rights litigation led to the closing of both several years ago, is now looked for, all legal difficulties having been overcome. The Richmond-Eureka-Summit group will continue shipping ore to Trail. The Ruth-Hope group will keep its mill going and send out both silver-lead and zinc concentrates. Up Cody Creek the several mines mentioned in the last number of the Journal, are continuing to make progress. Similarly, the outlook is good for the Slocan Lake district mines.

There is little that is new to report relative to mines in Nelson mining division, conditions being much the same as described last month. A resumption of work at the Queen Victoria mine, situated a few miles west of Nelson, and which was acquired by the Consolidated Mining & Smelting Company about eighteen months ago, has been announced. In both Ymir and Sheep Creek camps there is activity, especially in the latter, developments being encouraging. The prospective sale of the Queen mine, near Salmo, has been reported; this is a gold-quartz property, having a 20-stamp mill.

Rossland mines show little change. The Le Roi is still working, but its ore production figures remain small as compared with those of most earlier years, during which it has been worked. Le Roi No. 2 maintains its output regularly. The Consolidated Company's mines are shipping a considerable quantity of ore to Trail every week. Some ore was lately shipped from the Nickle Plate, which in the busier days of Rossland camp was one of its best known mines, but has not been heard of in recent years until now. The Consolidated Company's smelter is gradually increasing its tonnage of ore treated and quantities of metal produced. Among its receipts last month was a quantity of concentrate from the Hedley Gold Mining Company's 40-stamp mill at Hedley, Similkameen. Rossland men are developing the Fife mine, a copper-gold property situated on the Boundary slope of the divide between the Columbia and Christina Lake valleys.

In the Boundary District.

The British Columbia Copper Company's mines and smeltery will be operating again before these notes shall be printed, labour troubles having been got over for the time, and sufficient men having been obtained to take the places of those who left the district when the strike took place. Mr. Paul S. Couldrey, formerly manager of the Le Roi No. 2, Limited, Rossland, and for rather more than a year superintendent of the B. C. Copper Company's Mother Lode mine, goes to Peru to take charge of a big mine there owned by the company for whom Mr. A. B. W. Hodges, late local manager for the Granby Company, is now general manager. Mr. Couldrey has been one of the hardest working, and most successful mine managers (successful as regards results of his mine development work) in this province, so his departure is much regretted. He was not given a fair deal by the English mining engineers who have the direction of Le Roi No. 2 affairs, but he has the satisfaction of knowing that his good work is appreciated by other large companies, and his services sought after.

The Granby Company lately had an examination made of some mineral claims situated in Franklin camp, up the North Fork of Kettle River, 50 miles or thereabouts, from Grand Forks. The company's 4,500-ton smeltery is at Grand Forks. There are some big ore-bodies in Franklin camp, but the value of the ore in bulk has not yet been ascertained, for railway transportation facilities have not yet been provided for this camp. Rails have been laid for a distance of 17 or 18 miles from Grand Forks, and recently it was announced that a second section, of 10 miles, of line would be constructed this summer, but a commencement with this work has not yet been made. There will still be a gap between the far end of the second section of the railway and Franklin camp mines, so that there is no immediate prospect of ore being shipped thence to a smelter. Owners of mineral claims are earnestly hoping the Dominion Geological Survey will give the camp attention during the summer, so that a map of the district and a report may be issued with as little delay as shall be practicable, for no official information relative to this part of the Boundary country has been published since Mr. Brock's account of his short visit in 1907.

Melting snow is in some measure hampering the shipment of ore from Phoenix camp mines, the surface of the ground being soft, and work above ground consequently hindred. Another disability slightly affecting the mines now that spring is well advanced is that numbers of men who work at the mines throughout the winter go into the hills prospecting or doing assessment work on their mineral claims, so there is a temporary shortage of men. Under these conditions it has been found advantageous to run only six of the eight blast furnaces at the Granby smelter, so that costs may not be made higher at the company's mines by requiring them to ship ore up to the full capacity of the eight furnaces at the smeltery. As soon as normal conditions shall prevail, it will be practicable to operate all eight blast furnaces without inconveniencing the mine officials to keep up a full supply of ore. The tonnage with six furnaces in blast is about 3,400 tons of ore per diem.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax.—Mr. A. A. Hayward, general manager of the new scheelite mines near Moose River, Halifax County, has named the new settlement, Scheelite. New roads have been surveyed and the camp buildings are practically completed. Four shafts are being sunk. Three of these showed no scheelite on the surface, but are now in rich ore. The ore will be hauled to railway by means of a traction engine and trailer. Hugh McAskill is foreman.

Stellarton, May 30.—The executive of the Board of Mining Examiners for the province will meet in Stellarton on Wednesday, June 1st, for the purpose of preparing questions and other work preliminary to the annual examinations to be held during June, at the various examination stations throughout the province.

ONTARIO.

Ottawa.—During the last fiscal year the total bounties paid by the Government amounted to $1,808,533. The bounties on pig iron totalled $573,968, on a total production of 740,244 tons, of which 547,063 tons were made from Canadian ore. The steel bounty amounted to $695,762 on a total production of 740,390 tons. The bounty on wire rods was $538,812 for a total output of 89,802 tons.

Cobalt, May 30.—In the cross-cut northeast from the 225-foot level, the No. 2, one of the principal veins of the Coniagas, has been cut in the past week. The Coniagas veins, though small, are so regular that there was some surprise expressed when the lead was not tapped at precisely the spot expected, but it was found later. It is at the 225-foot level four inches wide of smaltite ore heavy with native silver and running several thousand ounces to the ton.

Cobalt.—With the starting of the new plant of the Trethewey Mining Company, thirteen mills are in operation in the Cobalt district. The skips from the No. 2 shaft are now running regularly up the 650-foot tramway to the Trethewey mill and the plant is working with the exception of some minor adjustments at almost full capacity.

Toronto, June 7.—A deputation of mining men waited on Hon. Frank Cochrane, Minister of Lands, Forests and Mines, representing the holders of iron ore claims in the Mattagami River region, some 80 miles north of Cochrane, to ask for an extension of time for developing their claims. Those present were Messrs. W. F. Powell, Ottawa; R. J. Flaherty, H. P. Glidden and John Martin, of Cobalt. The region has been inaccessible hitherto and it is only the last few months when attention has been attracted by the coal discoveries in the district to the west, that hope is felt that there may be an extension of the T. & N. O. Railway line there. The iron ore is recognized as valuable and needing only transportation facilities to enable machinery to be taken in and the ore brought out to the smelter. The mine owners feared that the Government might cancel their claims.

BRITISH COLUMBIA.

Vancouver.—The first gold brick from the Queen Charlotte Islands has been delivered to the Dominion assay office in this city. It was the output of the Early Bird free milling group, on the west coast of Moresby Island, and is the result of a day's run of a five-stamp mill. The value of the brick is $400. The mining property is owned by Messrs. J. McLellan and F. J. Bourne, M.E., of Cobalt, who acquired it some three years ago. There is a 100-foot shaft on the property and 250 feet of drifting. Commencing with a two-inch stringer, which has now widened to six inches, in places the vein gives exceptional values. On the surface the vein has been exposed for 250 feet.

Mr. Bourne, who has been in the city for a few days, en route east, considers the proposition a very promising one and he is very optimistic regarding the mining industry on the islands.

Creston, May 28.—An excursion party of McGill College mining students, numbering some twenty-five, in charge of Dr. J. B. Porter, Professor of Mining at McGill University, arrived in Creston at 9 o'clock on their way to Nelson. This party is making its annual tour of Canada, with a view of visiting the principal mining camps. Last year they visited mining camps in Nova Scotia and New Brunswick. Before reaching Creston on this tour they had visited Cobalt and Sudbury. They have also visited Coleman, where they stayed seven days, as well as Moyie, where they remained six days. These students, who are mostly three-term men, are being distributed among the various mining camps in British Columbia this season, where they can obtain a practical knowledge of the way the work is done. After visiting the mines at Nelson, they will proceed to Phoenix, and from there to Greenwood and Rossland. It is expected that the tour will be finished by June 2nd. By that time all of the students will have been distributed among the various mining camps. Dr. J. B. Porter, who is in charge of the party, appears to be a great favourite with the students.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

London, June 1.—Six miners were overcome by fire damp in a pit at Croy, Dumbartonshire, and were gallantly rescued by companions, one of whom collapsed during the process.

Final attempts were made on May 21st and 22nd to penetrate the workings of the mine by the return airway, but they proved absolutely impracticable. Experts were enabled by the aid of breathing apparatus to get to a point about 500 yards from the seat of the outbreak in No. 3 junction; but they were obliged to return by reason of the intense heat, after having passed through a stroke of fume gas, which was succeeded by dense smoke. In consultation with the managers afterwards they very reluctantly came to the conclusion that there was absolutely no possibility of any of the men getting past the fire and the smoke and gas in the return airway.

It is quite certain that long ago all the imprisoned miners must have succumbed to the fumes that have been carried inbye, and the quickest way of recovering the bodies will be to exclude all air. Although it is thought that the fire may have been in a measure subdued, any admission of air would kindle the slumbering embers and produce perhaps further regrettable consequences.

The fund for the relief of the sufferers has reached £23,150.

ROUMANIA.

During March the total exports of petroleum and petroleum products from Roumania amounted to 36,151 tons, as compared with 25,637 in March, 1909. In the same period the production amounted to 111,456 tons, as against 109,199 tons produced in February.

RUSSIA.

The Baku Black Sea Company has commenced the construction of the pipe line which will bring oil from the various plots

of the company to the iron tanks erected in the neighbourhood. This will be the first pipe line in the Maikop district.

Great activity is reported in the export of petroleum products from Baku. The loading of tankers and sailing boats is proceeding with great speed, and some twenty boats are waiting their turn at the wharves of Messrs. Nobel Brothers and the Caspian Society.

The Surakhany spouters are increasing in number in addition to the spouters on the properties of Benkendorff and of the Baku Petroleum Company. The well No. 5, of Messrs. Mirzoeff Brothers started spouting on the 27th March last from a depth of 1,190 feet. The yield in oil averages from 15,000 to 20,000 poods a day. On the 11th April another spouter on the field of the Baku Petroleum Company broke out from a depth of 1,568 feet, producing 200,000 poods a day. It is now nearly three months since the spouter on the Benkendorff's property broke out, having approximately produced over 5,000,000 poods of petroleum. The yield of oil averaged from the start about 300,000 poods a day. For about a month it kept at the level of 100,000 poods a day, falling finally to 35,000-40,000 poods a day.

SOUTH AFRICA.

A cablegram from Johannesburg states that during April the mines of the Rand alone (that is, excluding outside mines) crushed 1,763,104 tons. The average working expenses per ton were 17s. 6d., the profit per ton was 10s. 7d., and the aggregate profit £932,975. Below will be found similar figures for the previous three months, from which it will be observed that April shows no marked variation. The profit per ton is 3d. higher and the total profit about £19,000 more than for March.

UNITED STATES.

Seattle, Wash.—Officers of companies operating steamships to Alaska points on the Behring Sea estimate that 15,000 people will leave Seattle for Nome and St. Michaels on the early sailings, drawn by reports of rich gold discoveries in the Idatarod gold fields.

The first regular liner to leave Nome will sail from Seattle to-morrow; every berth had been sold weeks in advance. Men of wealth have been compelled to take accommodations in the steerage, and there is a waiting list at the steamship offices larger than the combined capacity of the northbound steamships. So great is the rush to the North that passengers and freight officers of the Alaska steamship lines say the movement, which amounts to a stampede, has been equalled but once in the history of the North, and that during the Klondyke rush thirteen years ago.

Bishop, Cal., June 2.—Two shifts are now at work in the property of the Bishop Creek Mining Company. The water has been lowered to the second level, which is 290 feet below the surface and the pump will be transferred from the upper station to this second level preparatory to continuing the development work at this point. A little later in the season, after most of the snow has melted and there will be less trouble from seepage water, it is probable that another hundred feet of shaft will be sunk to run a third level and further open up the ore body.

Los Angeles, May 31.—On three days of last week the Lakeview gusher was carefully measured and its flow was found to be 48,000, 49,000 and 51,000 barrels for each 24 hours. It broke out on March 21st; consequently, at the moderate estimate of only 40,000 barrels a day, it has produced up to date the enormous amount of 2,600,000 barrels of petroleum.

Montrose, Colo., May 31.—News is received here of a rich strike of vanadium ore in the Newmire district. This is a new district, and the veins now are only in process of development. A mill for the reduction of the ore is now in operation at Newmire, and the latest strike will necessitate an addition to the mill. The force of men working on the veins will be largely increased at once, and development work will be prosecuted with vigour.

Recently a consignment of this ore was sent to London, Eng., where it was to be used on trial by a big British steel manufacturing concern. The shippers were assured that if this ore proved satisfactory England would become a large consumer of western slope vanadium ore.

Cripple Creek, Colo., June 1.—The output of the mines of the Cripple Creek district for May was 57,105 tons, with gross bullion value of $1,349,502.50.

With the exception of the Golden Cycle mill, all treatment plants reported an increase, and it is understood that while heavy tonnage was shipped to the Cycle plant, the ore was bedded down for future treatment.

There has been no decrease in output, and the average value of the ore was 60 cents per ton higher. The value per ton for all grades of ore treated was $23.63, as against 23.03 in April.

Joplin, Mo.—The 200-ton concentrating plant of the Missouri Zinc and Lead Mills Company, on a 20-acre lease of the Smith ground at Cave Springs, west of Joplin, has been finished and is rounding into steady operation, early runs having showed the machinery to be working nicely.

Unlike the ore run worked by the Herald Zinc and Lead Company, to the north, the Missouri Company has mineral at 100 feet, while in the adjoining mile the ore run is worked below the 200-foot level. Both zinc and lead are found in the new mine.

MEXICO.

Mexico City, June 2.—The reduction mill of the Santa Rosa Milling & Mining Company operating the old Chinos group of mines on the Pelayo ranch, near Ayutla, State of Jalisco, will be reconstructed with a capacity of 100 tons of ore per day by the addition of new machinery received at Ameca a few days ago. The new appliances have been forwarded to the mines and are now being set up in the mill building of the company. They consist of a No. 5 Huntington ore mill, four Overstrom tables, two Woodbury tables, two Richards classifiers, two large Callow settling tanks, together with a number of smaller apparatus. The new machines will be run in connection with the old ten-stamp mill which has been on the property for several years. Steam power will be used.

Chihuahua, Mex.—The Lepanto mine at Naica is said to be shipping 2,000 tons of silver-lead ore per month.

The Rio Tinto Copper Company has accumulated 2,500,000 pounds of copper during the past year. The ore will be put through the converter when the new plant is put in operation about July 1st.

The Reina silver mine, in the Cusihuiriachic district, will soon change ownership and management, according to reports which are current here.

Pachuca, Mex.—Engineer Azan has gone to Ixmiquilpan to make a complete survey for the installation of the 5,000 horse power hydro-electric plant for which his firm holds the concession. The plant will be situated some 20 kilometers east of the town of Ixmiquilpan and Actopan, in all of which districts large denouncements of mineral lands are being constantly made.

Mexico City.—For months past there has been a serious drawback to the mining interests in the Etzatlan, Hostotipaquillo and neighbouring districts in the state of Jalisco by the failure of the electric power company, the Compania Hidroelectrica e Irrigadora to make good its proposal of supplying power for mine and mill purpose.

This delay was caused by a condition of affairs that was extremely unfortunate and worked some stress upon the mining concerns alluded to. However, all these circumstances have been overcome and construction has been actively resumed on the transmission line and is being pushed energetically and there is no doubt that by October at the latest there will be an abundance of power.

COMPANY NOTES.

VAN ROI MINING COMPANY, LIMITED.

The following cable was received at the London office from the company's managers at Rossland:

"Mill Report for Month of April: Total amount crushed, 3,269 tons, yielding 140 tons lead concentrates, assaying 210.7 ounces silver, 62.6 per cent. lead, 10.8 per cent. zinc; and 100 tons zinc concentrates, assaying 74.2 ounces silver, 3.4 per cent. lead and 43.9 per cent. zinc. Total approximate value $19,834 (£4,089). Mill ran 568 hours.

"Estimated expenditure for corresponding period, including mining, milling, developing, and other expenses, $17,000 (£4,505).

"No. 4 Level (main vein driven eastward 45 feet). Raise east of main stope successful—are now stoping in.

"No. 4 Level (continuation of Footwall Fork) south vein, west part: width 3 feet, 19 ounces silver, 9 per cent. lead, 9½ per cent. zinc. East part: width 2 feet, 7½ ounces silver, 4½ per cent. lead, 5¼ per cent. zinc.

"Crosscut to south vein following Diamond Drill Hole No. 4. Crosscut has reached reef."

INTERNATIONAL NICKEL DIVIDEND.

The International Nickel Company has declared an extra dividend of 25 per cent. on the common stock, payable July 15 to stockholders of record June 6.

At a special meeting of the directors it was resolved that this extra dividend be paid out of the surplus earnings of the company for the period from April 1st, 1906, to March 1st, 1910, after the payment of the full dividend of 6 per cent. on the preferred stock in each and every year of such period, and the dividends heretofore declared and paid on the common stock during the fiscal year ended March 31st, 1910.

The company offers to its stockholders pro rata for subscription at par $2,670,000 of common stock heretofore unissued as follows: Each stockholder of record of common or preferred stock at close of business on June 6th, may subscribe for new common stock to the extent of 15 per cent. of his holdings of each class of stock.

Since April 1st, 1906, the company has earned after charges on account of bond interest, sinking fund, depreciation and dividends on common and preferred stock, $2,855,339 annually. Of this $487,977 has been declared in common dividends, leaving available $2,367,361 in the surplus account.

The Dominion Steel & Coal Corporation has issued the following circular to Steel and Coal shareholders:

"The proposed issue of stock of this corporation in exchange for the common stock of the Coal Company and Steel Company has now been arranged. The new stock has been listed on the Toronto, Montreal and Boston Stock Exchanges; transfer agents and registrars have been appointed at these places, and a large number of shares have already been exchanged.

"Shareholders who intend to accept the proposed exchange are respectfully requested to deposit their stock with one of the trust companies mentioned in the form sent on 20th April, or to send the certificates direct to the National Trust Company, Limited, Toronto, who will at once send certificates for stock of the corporation in exchange.

"It is intended to close the transfer books from the 16th June to the 2nd July, and only shareholders of record at the closing of the books will be entitled to the payment of $1.00 per share, accruing on 1st July. Shareholders who are prevented by absence, etc., from exchanging their shares in time should communicate the facts to the secretary for consideration by the board.

"A meeting of the shareholders is to be held on Friday, the 17th June, for the election of directors."

The directors of the McKinley-Darragh Company have declared a three per cent. quarterly dividend for the entire ensuing year, payments to be made in July, October, January, and April. An extra dividend of two per cent. has been also declared for the July period.

This is the first time that a dividend has been declared by a Cobalt company for an entire year ahead of time.

The Calumet & Hecla Mining Company has declared a quarterly dividend of $7 a share. The last previous disbursement was $8 a share, and at this time a year ago was $8 a share. The dividend is payable June 28th to stock of record June 4th.

STATISTICS AND RETURNS

The output of the Dominion Iron & Steel Company for the fiscal year ending May 31st shows considerable improvement over that of the previous like period. Following are the comparative figures:

	Gross Tons	
	1908-09.	1909-10.
Pig Iron	248,097	255,932
Steel Ingots	273,646	302,761
Blooms	246,323	269,810
Rails	133,064	147,948
Rods	50,554	81,001

The output of the Dominion Coal Company during May was 296,000 tons.

TYEE COPPER COMPANY, VICTORIA, B.C.

The return of results of operations at the Tyee Copper Company's smelting works at Ladysmith, Vancouver Island, B.C., for the month of April, with one furnace in blast is as follows: "Furnace ran 28 2/3 days and smelted 7,492 tons, producing 625 tons of copper matte, valued at $71,000." No ore was smelted at these works in January, owing to there having been repairs and improvements in progress that month. The figures for three consecutive months to May 1st are as follows:

Month.	Days Run	Tons Smelted.	Tons Matte.	Value.
February	16	4,354	330	$48,190
March	18 1/3	4,750	270	37,000
April	28 2/3	7,492	625	71,000
Totals	63	16,596	1225	$156,190

COBALT ORE SHIPMENTS.

Shipments of ore from Cobalt Camp last week were 1,200,029 pounds, divided among nine mines. La Rose and Kerr Lake were the big shippers. Shipments for the year to date are 23,647,609 pounds, or 11,823 tons. Shipments for the week and year in pounds of ore are:

	Week ending May 28.	Since Jan. 1
Beaver		120,450
Buffalo	57,780	883,368
City of Cobalt		363,835
Chambers-Ferland	58,300	349,360
Cobalt Lake		196,000
Cobalt Townsite		68,000
Colonial		107,260
Coniagas		623,796
Crown Reserve	148,315	2,529,610
Drummond		664,200
Hargraves		41,800
Hudson Bay		123,695
Kerr Lake	304,336	3,382,337
King Edward		174,966
La Rose	380,988	5,204,199
McKinley-Darragh		1,246,599
Nipissing	56,000	4,428,541
O'Brien		648,046
Peterson Lake		270,450
Provincial (Govt.)		65,000
Right of Way	58,000	654,777
Silver Cliff		117,510
Temiskaming	80,000	501,830
Trethewey	56,300	503,950
Waldman		63,992

La Rose continues to lead the Cobalt mines in tonnage, shipping twice as much ore last week as Crown Reserve or Nipissing, the next largest shippers. Ore shipments for the week ending June 3rd were 1,166,724 pounds, or 583 tons. Total shipments from January 1st to June 3rd were 24,814,333 pounds or 12,407 tons. Shipments for the week and year in pounds of ore are:

	Week ending June 3.	Since Jan. 1.
Beaver		120,450
Buffalo		883,386
City of Cobalt		363,835
Chambers-Ferland	56,000	405,650
Cobalt Central		293,286
Cobalt Lake		196,500
Cobalt Townsite		68,000
Colonial		107,260
Coniagas	63,280	687,060
Crown Reserve	188,486	2,718,068
Drummond		664,200
Hargraves		41,800
Hudson Bay		123,695
Kerr Lake	60,380	3,442,717
King Edward		174,966
La Rose	377,390	5,582,381
McKinley	151,140	1,397,719
Nipissing	127,586	4,556,127
O'Brien		648,046
Peterson Lake		270,450
Provincial (Govt.)		65,000
Right of Way	82,500	757,257

OPEN-HEARTH STEEL PRODUCTION IN 1909.

The American Iron and Steel Association has just compiled its statistics for the production of open-hearth steel ingots and open-hearth castings in 1909. They show that the total was

14,493,936 gross tons, against 7,836,729 tons in 1908, an increase of 6.657,207 tons, or 85 per cent. The production in 1909 was much the largest in the history of the industry and exceeded that of 1907, the next largest year, by 2,944,200 tons, or 25.4 per cent. In 1908 the production of open-hearth steel for the first time exceeded that of Bessemer steel, the totals in that year being 7,836,729 tons and 6,116,755 tons respectively. For 1909, the figures were 14,493,936 tons and 9,330,783 tons, respectively. The total production of basic open-hearth ingots and castings was 13,417,472 tons, while that of acid open-hearth ingots and castings was 1,076,464 tons.

TORONTO MARKETS.

Metals.

June 8.—(Quotations from Canada Metal Co., Toronto.)
Spelter, 5½ cents per lb.
Lead, 3.65 cents per lb.
Antimony, 8 to 8½ cents per lb.
Tin, 34.50 cents per lb.
Copper, casting, 13.75 cents per lb.
Electrolytic, 13.75 cents per lb.
Ingot Brass, 9 to 12½ cents per lb.

June 8.—Pig Iron.—(Quotations from Drummond McCall Co., Toronto.)
Summerlee No. 1, $23.50 to $24.00 (f.o.b. Toronto).
Summerlee No. 2, $23.00 (f.o.b. Toronto).

NOTICE

STUDENTS EMPLOYMENT REGISTER,

The CANADIAN MINING JOURNAL has opened an employment register for students taking mining or metallurgical courses at Canadian Universities or Technical Colleges. Mine operators who wish to employ students during the summer months are requested to communicate with the Business Manager.

Students are requested to send in their names, along with brief records of experience. These will be filed and no effort will be spared on our part to place applicants in immediate communication with possible employers.

This year we are building **Green Silk Tents** which we believe will be popular with Tent users. They are no heavier in weight but have an advantage over white color, for **sleeping purposes** so that one is not awakened by the early rising sun, and can sleep in comfort. All sizes at reasonable prices.

We are sole manufacturers of STANDARD WEATHERPROOF DUCK TENTS, Tarpaulins, etc. For Camp Beds, Chairs, Stoves, Grey Blankets or any other supplies. Send your orders to

J. J. TURNER & SONS, - Manufacturers,
Agents Everywhere PETERBOROUGH, ONT.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

GEOLOGICAL SURVEY

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, and with many local areas and special subjects.

MARITIME PROVINCES

The whole of Cape Breton, and a large portion of the coal and gold fields of Nova Scotia, have been reported upon, and mapped on a scale of 1 mile to 1 inch. The remaining portions of the Province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter Provinces, mapped on a scale of 4 miles to 1 inch.

QUEBEC

Quebec, south of the St. Lawrence, has been reported upon, and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the Province north of the St. Lawrence are also available.

ONTARIO

A large part of the Province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

THE PRAIRIE PROVINCES

Geological maps and reports have been issued covering the greater part of the Provinces of Manitoba, Saskatchewan, and Alberta.

BRITISH COLUMBIA

The southern portions of British Columbia, as well as other parts of the Province, have been reported upon and mapped.

YUKON

Many of the important areas in the Yukon have been reported upon and mapped.

THE NORTH WEST TERRITORIES

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of a report or map will be sent to Canadian applicants free of cost, and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

Applications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.

THE FOLLOWING GEOLOGICAL MAPS HAVE RECENTLY BEEN ISSUED:

CANADA

1084. General Geological Map of Canada. Scale 100 miles to 1 inch.

NOVA SCOTIA

1019. City of Halifax Sheet.

1025. Waverley Sheet.

1037. Windsor Sheet.

The above sheets belong to the regular series of Nova Scotia map sheets on a scale of 1 mile to 1 inch. The first includes Halifax City and Harbour, the second the Waverley Gold District, and the third Gypsum Quarries.

ONTARIO

1023. Geological Map showing position of Corundum-bearing rocks in Central Ontario.

1076. Gowganda Mining Division.

This map besides representing the geology of the Gowganda area, represents the geography of a considerable area to the east and north.

980. Portion of Algoma and Thunder Bay districts, Ontario, 1908. W. J. Wilson.

1081. Region lying north of Lake Superior between the Pic and Nepigon Rivers, Ontario, 1906. W. H. Collins.

BRITISH COLUMBIA

1002. Geological Sheet, Special Map of Rossland.

This map, on a scale of 400 feet to 1 inch, besides accurately indicating the topographical and cultural features, shows the geology and location of veins.

1004. Geological Sheet, Rossland Mining Camp. Scale 1200 feet to 1 inch.

1074. Sketch map of Sheep Creek Mining Camp, West Kootenay, B.C., scale 1 mile to 1 inch.

YUKON

1041. Geological and Topographical Map of Whitehorse Copper Belt. Scale 1 mile to 1 inch. Also several detail maps of same belt.

NOTE.—Maps recently published may be had on linen cloth, for use in the field, at 10c. per copy.

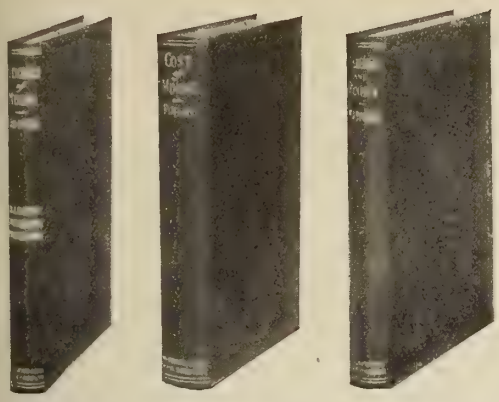
REPORTS

1072. Summary Report of the operations of the Geological Survey for year 1908.

1085. Descriptive Sketch of the Geology, and Economic Minerals of Canada. G. A. Young. Introduction, R. W. Brock.

1075. Gowganda Mining Division, 1908. W. H. Collins.

1035. Coal Fields of Manitoba, Saskatchewan, Alberta, and Eastern British Columbia, 1908. D. B. Dowling.



1050. Whitehorse Copper Belt, Yukon. R. G. McConnell.

NEW CATALOGUE

1073. Catalogue of Publication 1843—1909.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

The Three Most Important Mining Books of Recent Years

They Cover

PRINCIPLES—ECONOMICS—METHODS

Principles of Mining. By H. C. Hoover, $2.50 (10/6) net postpaid.

The principles of mining as developed by modern science and business methods are here fully discussed under the general headings of Valuation, Organization and Administration. Important chapters cover investment from the public's standpoint, and the character, training and obligations of the mining engineer.

Cost of Mining By James R. Finlay. $5.00 (21s) net, postpaid.

An economic investigation of the cost of scientific. profitable mining. It contains valuable data obtained from official reports of the mines producing 75 per cent. of the metal under discussion. Detailed analyses cover cost of mining *coal, iron, lead, zinc, copper, gold and silver.*

Timbering and Mining. By W. H. Storms, $2.00 (8/6) net, postpaid.

Deals with practical methods, not theories. A straightforward account of the best, safest and most economical methods employed in the leading American mines.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are: Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows:

All mines belong to the Goverment of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unserveyed territory, is open to prospecting.

Miners' Certificates good for a calendar year may be obtained by sending $10.00 to the Department of Mines. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minium being 40 acres in unserveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of $10.00 plus a yearly rental of $1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed territory may be purchased as a mining concession at the price of $20.00 per acre if within 20 miles of a railway in a straight line, or $10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

The Hon. Minister of Colonization, Mines and Fisheries
Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,03 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land ha been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in th Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed b Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

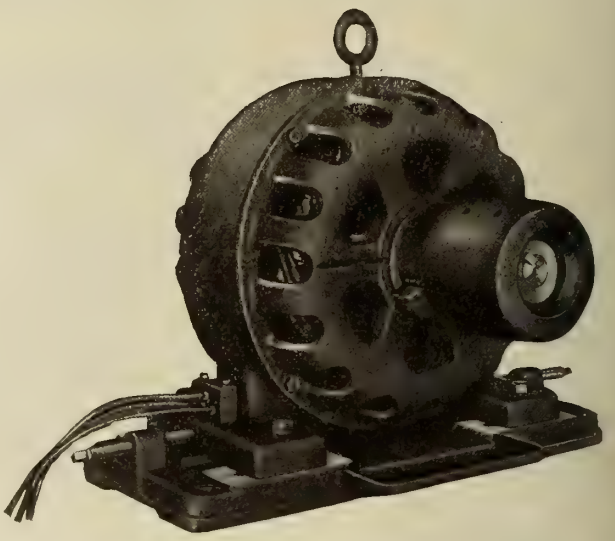
MONCTON, N.B.

Westinghouse

Type "CCL" Induction Motors

The only wearing parts of



Type "C C L" Motors—the bearings

are designed and constructed to withstand years of the severest service without other attention than an occasional filling of the oil wells.

On motors above 5 horse power capacity the bearings are split, the interior of the housing forms the bearing shells which are lined with a special grade of bearing metal, the bearing housings are clamped between the halves of the bracket and are held in perfect alignment with each other by dowel pins.

On motors below 5 horse power capacity the bearing housings are cast solid with the bracket, and the bearings are bronze bushings pressed into place and pinned.

Each split bearing has two oil rings; the solid bearings one. The lower part of the housing forms an oil well from which oil is carried by the rings to the top of the shaft and distributed through grooves to all parts of the bearing, thus keeping it flooded with oil while the motor is in operation. **Ask nearest office for Circular 1118. It tells all about Type "CCL" Induction Motors.**

Safety Fuse, Electrical Fuses, Batteries, and other Accessories.

Three Post Magneto Electric Blasting Machine

NOBEL GELIGNITE

It always breaks cleanly to the bottom of the drill holes and is free from fumes of any kind. Equal to 75% Dynamite and is sold at a price producing very much better results in terms of Rock Broken or Extracted and money spent.

"WINTER BRAND" DYNAMITE

Is only one strength, if anything, a little stronger than 50% Dynamite. **It does not freeze,** or rather, explodes with perfect efficiency when frozen **and needs no thawing.**

"AUTUMN BRAND" DYNAMITE

Is packed in all the usual percentages. The powder is similar in appearance, character and effect to ordinary Dynamite, except that the freezing temperature of the Nitro-Glycerine is reduced from 42° F to a little under 30° F.

PERMITTED EXPLOSIVES for Coal Mines
Nobel Monobel, Saxonite and Carbonite.

A letter or telegram addressed to the head office or any of the following agencies will receive prompt attention.

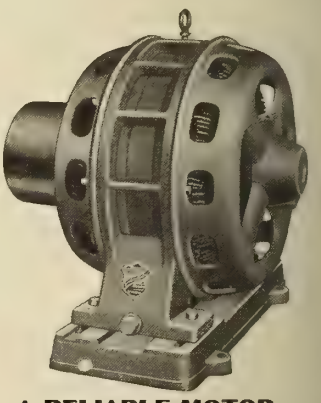
ELECTRIC POWER

FOR

MINING OPERATIONS



HYDRO-ELECTRIC PLANTS.

360 H.P. Water Wheel and 250 K.W. Alternator, with auxiliary apparatus, built by Allis-Chalmers-Bullock Ltd.

Electric drive is the most convenient and the easiest available power for mining operations. We are the only firm in Canada which builds complete hydro-electric plants including water wheels, generators, transformers and all auxiliary apparatus.

Our induction motors are designed to withstand hard usage and are especially suitable for driving rock crushers, stamp mills, crushing rolls, hoisting engines, tube mills, turbine pumps, jigs, vanners, etc.

A RELIABLE MOTOR.

Renold Patent Silent Chain

is constructed on sound, simple principles, and does not require expert knowledge to either install it or make a joint.

Spring Cushion Sprocket with Cover off.

For drives of a pulsating nature, Spring Cushion Sprockets are furnished, in which springs are interposed between the boss and the rim, thus absorbing the fluctuations of the load, preventing the shocks from being transmitted through the machinery. By their use chains are being successfully applied to drives of an extremely severe nature.

JONES & GLASSCO

Sole Canadian Agents **MONTREAL**

"CLEVELAND" STOPE DRILLS

EFFICIENCY:—Of course you want the stope drill which has the highest efficiency, but you must pick out the one that will have as high an efficiency a year from to-day. Isn't it true that your stope drills decrease steadily in efficiency as they grow older?

REPAIRS:—Repairs which must be made from time to time after the part has given long and satisfactory service, are not a source of dissatisfaction, but dont you find that your stope drills are constantly needing something new?

DRILLING CAPACITY:—As long as your stope drill will put in sufficient holes per shift to drill up your stope there is no argument in favor of your changing to our drill just because it will drill faster. We know that. But we know that the "CLEVELAND" Stope Drill will do as much work per shift when it is one year old as it will when one week old, and that is what you want, isn't it?

THE "CLEVELAND" Whether you purchase your stope drills after considering efficiency, repair cost, or drilling capacity, the "Cleveland" should be the stope drill you specify, for its design is such that the initial efficiency is the highest possible in an air tool, and the piston and valve action are so related that the "Cleveland" is just as efficient when it is a year old as when it is brand new; we **know**, and our information is gained from hundreds of installations that the "CLEVELAND" will cost less for repairs **per year** than any stope drill made; a 30 day trial will convince you that the "CLEVELAND" will drill as much per shift as any other stope drill, and we have machines always in stock ready to ship for trial if you will drop us a line. As you have everything to gain and nothing to lose, why not investigate NOW?

David Philip, 291½ Portage Ave., Winnipeg

CHOOSE THE RIGHT DRILL
FOR YOUR PARTICULAR CONDITIONS.

If too small, your drill holes will not be large enough or deep enough to shoot the rock economically; or your repairs will be unduly high.

If too large, labor and power will be excessive. Some valve-motions work well on heavy pressure, against hard even rock, others excel in soft or broken ground, on lower air pressure.

There is a Sullivan Drill which may be relied on to develop the highest possible efficiency and economy under any given set of working conditions.

As specialists in fitting drills to the service required, we solicit your inquiries.

Amatite ROOFING

NEEDS NO PAINTING

MOST ready roofings require special painting and coating, and unless this is done regularly, you are sure to have leaks and trouble right along.

If you use Amatite, nothing of the sort is required. You will have real roof protection *without painting* of any kind.

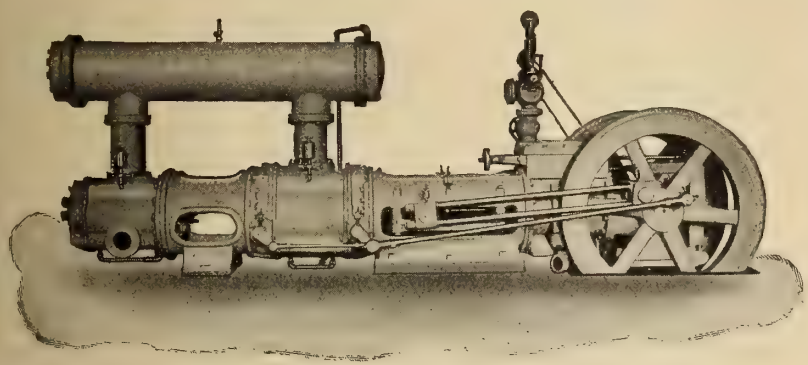
Amatite is made to stay waterproof and give protection year after year, without any thought or care on your part.

First—Because it is waterproofed with Coal Tar Pitch.

Second—Because it has a real Mineral Surface.

Amatite, owing to these features, is the most economical roofing made. Its first cost is low, and you are *saved* all future expense for repairs or paint because it will need neither.

If you haven't seen Amatite, write for a sample to-day. From it you will very quickly understand why it doesn't require painting; why it does not leak; and why it saves you money.



Address nearest office to-day.

Rand Class "C-2" Straight Line, Steam Driven Compound Air Compressors

High *efficiency, simplicity* and ease of accessibility are distinct characteristics of the Class C-2 Compressor.

Corliss Inlet Valves on Low Pressure Air Cylinder, giving exceptionally large direct intake areas, practically unlimited life, quiet operation at all speeds and sustained high volumetric efficiency.

A simple direct Corliss Valve motion in which all complications have been eliminated and best efficiency obtained.

Another Victory for the "DEISTER"

We are placing 180 Improved No. 3 Deister Slime Tables and 132 No. 2 Deister Sand Tables in the Miami Copper Company's mill, Miami, Arizona. This large order was the direct result of the showing made by the Deister Tables. The No. 2 Deister competing against all of the well-known makes of tables on the market—The Improved No. 3 Deister competing against vanners.

By eliminating teeth in the roller and rocker arm, our driving mechanism is now the most effective, noiseless and durable on the market.

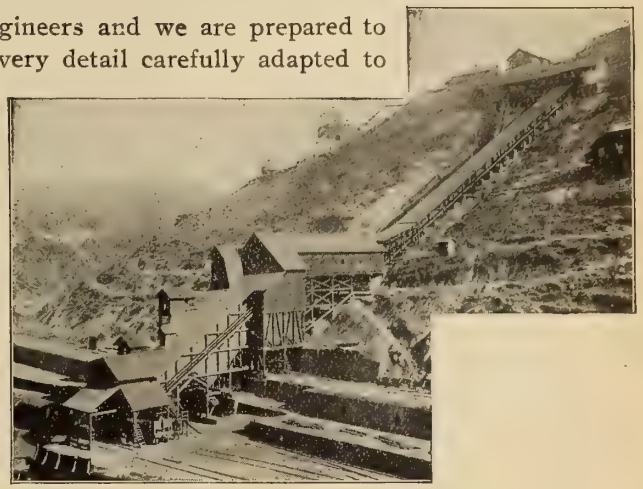
CYANIDE HANDBOOK BY J. E. Clennell

Over 500 pages, 6x9, illustrated, $5.00 (21s) net, postpaid



Mr. Clennell has been in close touch with the rapid developments of cyaniding. He has been instrumental, too, in many important discoveries, and his work in this field has taken him to the leading plants of the world. It deals generally with Cyanide and does not confine itself to the process alone. It is divided into nine main parts covering the subject more fully and exactly than it has heretofore been handled.

Especially noteworthy is the full treatment of recent developments and important phases heretofore *inadequately treated.*

HASTINGS COUNTY, ONTARIO.

The steady white light of Cobalt; the intermittent glare of Gowganda, Elk Lake, and Lorrain; and the immediate glamour of Porcupine, have thrown an undeserved shadow upon other mining districts of Ontario.

Geographically, Ontario is a vast and rich empire. But the history of its older mining regions has not been written. It is recorded vaguely in the memories of men who have seen three generations come and go.

Last week's visit of the Hon. Frank Cochrane, Minister of Mines for Ontario, to various points in Hastings County, was his ministerial inspection of that district. He was accompanied by Dr. W. G. Miller, Provincial Geologist; Mr. E. T. Corkill, Inspector of Mines; and by the editor of the CANADIAN MINING JOURNAL.

It were out of place to give here an itinerary of the brief journey. Our wish is rather to seize the opportunity to allude to the wonderful variety of minerals, and the unusual number of mining opportunities that exist even in the small section of Hastings County, examined during this visit.

It has become the habit of investors to look upon the mining districts of eastern Ontario as being either dead or moribund. How far this is from the truth is easily discovered by any person who takes the trouble to see for himself. And in adducing illustrations we confine ourselves to a part of Hastings County merely because space will not permit us to do more.

Within a radius of less than thirty miles three flourishing industries are established. At Sulphide, 136 miles east of Toronto on the C. P. R., a large acid manufacturing plant is producing steadily. Four years ago the Nichols Chemical Company began work here. Iron pyrites is mined locally and is purchased from several operators throughout the neighbouring country. This is probably the nucleus of an industry that will in time be second to none of its kind in North America. Deposits of clean pyrites, free from arsenic, occur over a large stretch of country. They wait the advent of the investor.

At Madoc, about fourteen miles to the east of Sulphide, is situated the only talc mill in Canada. The raw material is of exceptional purity. It is mined within a short distance of the town. The ground product now competes with unqualified success in the markets of the United States and Europe. As at Sulphide, so here, the introduction of hydro-electric power has cheapened operations materially. The capacity of the Madoc mill is soon to be doubled. At present the demand largely exceeds the output. Incidentally we may mention that the 125-foot shaft at the talc mine is a gratifyingly clean

piece of engineering, quite beyond the usual standard (or lack of standard) as regards safety and workmanship.

At Deloro, a short distance north of Madoc, is situated the plant of the Deloro Mining & Reduction Company. Here are treated ores from Cobalt, Ont. The recent addition of a complete cobalt-oxide plant brings this establishment into line with the most modern smelters. Cheap hydro-electric power is used here also.

The three places mentioned, Sulphide, Madoc, and Deloro, were the three principal points visited. They represent the three most advantageous centres of industrial enterprise. But the whole surrounding country is rich in such minerals as iron pyrites, copper pyrites, mispickel (nearly always carrying gold), fluorspar, actinolite, iron ores, slate, etc., etc.

We are strongly of the opinion that the whole countryside is worth exploiting. In many respects unique advantages are offered. Labour is plentiful, intelligent, and cheap. Hydro-electric power is available at remarkably low cost. The country is well opened up by railways. Farming and dairying are the chief present activities. Consequently living is cheap. Moreover, the natural beauty of the district, the plentiful supplies of clean water, and the negligible number of mosquitoes and black flies, are features that are positive inducements.

Local mining men have already accomplished much. But there is a limit to their capabilities—a limit set by lack of funds and an absence of outside interest.

We feel no hesitation in recommending such of our readers as are seeking channels of profitable mining investment to look carefully into the mineral deposits and the mining possibilities of Hastings County.

THE COMPRESSED AIR QUESTION IN COBALT.

In fairness to the Cobalt Hydraulic Power Company it was our intention to withhold comment upon certain difficulties that have been encountered by the users of hydraulically compressed air until fuller data should have been secured. Unfortunately, several journals and newspapers have published foolishly exaggerated accounts of these difficulties. Therefore it is but just to place before our readers the facts, such facts, at least, as are now available.

In the first place, we learn that the compressed air supplied by the Cobalt Hydraulic Power Company has been found absolutely satisfactory, except in such drifts and small stopes as are remote from shafts and in which ventilation has always been defective. In these places the "Taylor" air, owing to its deficiency in oxygen, does not readily support the combustion of a candle. "Sunshine" lamps, however, have been proved to work satisfactorily.

As our readers will remember, the plant of the Cobalt Hydraulic Power Company is situated at Ragged Chutes, on the Montreal River, nine miles from Cobalt. The Taylor system of air compression is employed, whereby advantage is taken of the huge volume of falling water to compress air hydraulically. The air is then transmitted to the mines of Cobalt through a system of 20-inch iron pipes.

When, some weeks ago, certain operators at Cobalt found that candles would not burn readily in restricted mine workings where this compressed air was used, it was thought that the asphaltum coating inside the pipe line was doing the damage. Brief reflection shewed that this explanation was untenable.

Light was thrown upon the question by the analysis of samples of air forwarded by the Hydraulic Company to Dr. J. T. Donald, of Montreal. It was found that the compressed air, instead of containing 20 to 21 per cent. of oxygen, contained only 17.7 per cent., the loss naturally being due to the solvent power of water in intimate and continued contact with finely divided air. This, in itself, is quite sufficient to account for the difficulty in using candles.

Upon the announcement of these analytical results alarmists at once predicted that the miners would not be able to work in air so deficient in oxygen. Not content with this, despatches were sent to the press describing purely imaginary instances of suffering. These had not even a colourable foundation in truth. No hardship has been experienced. Particular pains have been taken by those interested to investigate the effect of the air upon miners working in remote faces and stopes. Up to the present the unanimous verdict is that no evil effect is perceptible.

For the past four years "hydraulic" air has been in constant use at the Victoria copper mine, Michigan. Whilst here the same complication as to illuminants has been met and overcome, the miners have been in no way affected. Eighty-five analyses of samples of air from representative coal mines of Scotland have recently been published. Of these, twenty-six fall below 20 per cent. in oxygen contents. The lowest figure reported is 16.55 per cent. Hence conditions such as outlined are by no means unusual. But a marked difference exists in the case of Cobalt. Here air low in oxygen is encountered only in a few isolated workings. The condition is not general. Nor is it in any degree alarming.

Let us now look for a moment upon the other side of the question. The Cobalt Hydraulic Power Company has invested an enormous amount of money in installing the largest natural air compressor in the world. The boldness and vigour of its promoters are beyond praise. The undertaking was one that involved startling engineering difficulties. It has been carried to a successful issue. To Mr. Charles H. Taylor, the Canadian whose ingenuity made the whole thing possible; and to the men who put up the money, Cobalt is deeply indebted. To them, also, we take off our hat. They have supplied Cobalt with a better, cheaper source of power.

Of those persons who thoughtlessly or otherwise pub-

lish michievous untruths or damning half-truths concerning such an enterprise, we prefer to express no opinion. The postal authorities are decidedly more finnicky than they were in the palmy days of personal journalism.

LET THE PUNISHMENT FIT THE CRIME.

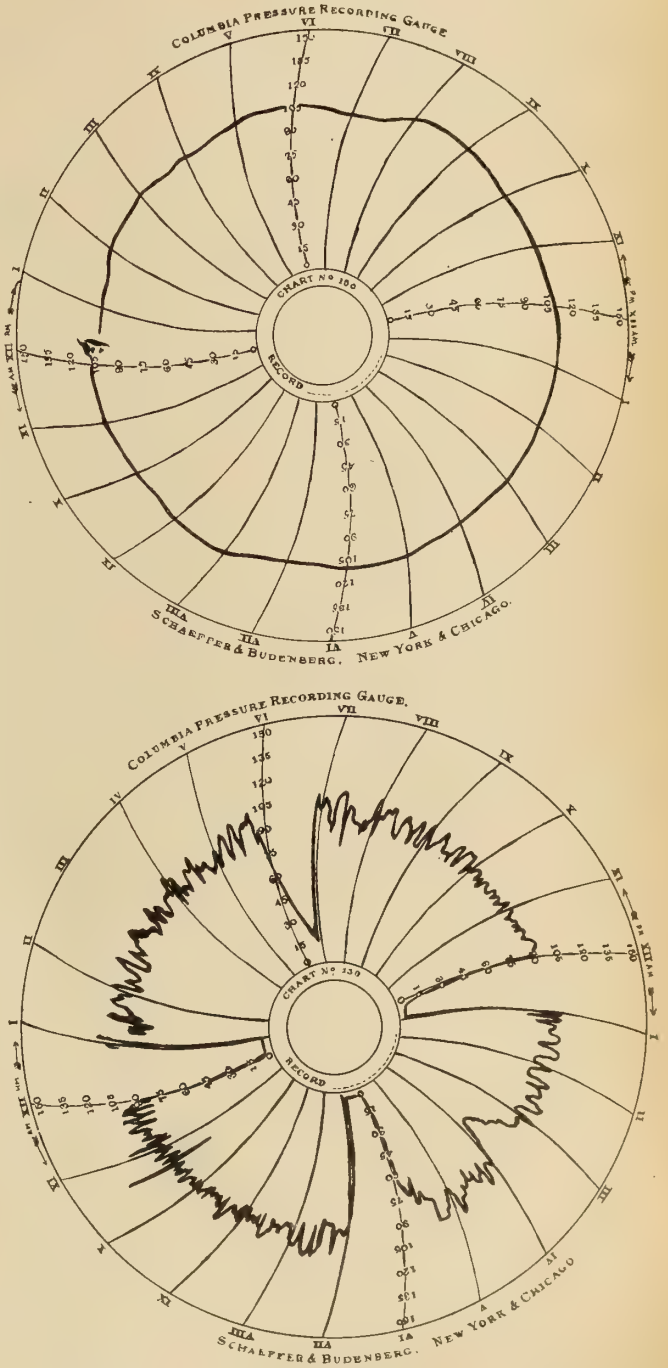
The punishment meted out to the men convicted of stealing Cobalt ores and to the local refiner convicted of purchasing these ores from unauthorized sellers, was totally inadequate. It consisted of nominal fines with light terms of imprisonment as alternatives.

We take it that legal punishment is inflicted as a deterrent of crime. Just how effective are the instances above quoted may be judged from the fact that as we go to press we learn that a large quantity of ore has been stolen from the Lucky Godfrey mine.

This miserable and demoralizing business will continue until a judge arises who is possessed of sufficient sense of proportion to make the punishment fit the crime. Anything short of this is inexcusable trifling.

CONCERNING ONE APPOINTMENT.

The appointment of Mr. H. E. Haultain to the position of Professor of Mining Engineering at the University of Toronto affords satisfaction to the mining public. During the past two sessions Mr. Haultain's position was that of associate professor. The translation, though necessarily tardy, is most welcome. The University is still far behind McGill and Queen's in its mining engineering department. Professor Haultain, vigourous though he may be, cannot do justice to the increasing number of students of mining. Toronto University is the largest and richest in the Dominion. The Province of Ontario derives more income from the mining industry than most of the other provinces put together. It should not require a surgical operation to convince both the Government and the University that a larger staff is required. Mining, ore-dressing, and metallurgy are totally distinct subjects of instruction. Were it not consumingly irritating, it would be laughable to observe that mineralogy and geology, two entirely subordinate sciences, are given far more attention than the industry that they are supposed to subserve.



EDITORIAL NOTES.

A hammer drill is being used successfully in sinking a new shaft at Sulphide, Ont.

Spectacular finds of gold have recently been made at Fifteen Mile Stream, Halifax, Nova Scotia.

Before many weeks shall have elapsed we hope to announce the appearance of a special edition of the CANADIAN MINING JOURNAL to be devoted largely to the Province of Quebec. Preparations are now afoot.

In this issue is concluded a remarkable series of articles on the iron and steel industries of Canada. The writer, Mr. Watson Griffin, has for years made a close study of his subject. Perhaps no other Canadian journalist is so well qualified to write of these basic industries as is Mr. Griffin. At an early date these articles will be published in pamphlet form.

TWO CHARTS.

Fig. 1 is a reproduction of a pressure chart showing the daily record of air pressure from the Cobalt Hydraulic Company.

Fig. 2 is a pressure record from the same mine when an ordinary air compressor was being used. The contrast is obvious. Readers are referred to our editorial pages for further comment on this subject.

CANADIAN IRON AND STEEL.

BY WATSON GRIFFIN.

IV.

In my last article I described the location of the raw materials of iron-making, coal iron and limestone, in the Maritime Provinces.

No very large bodies of good iron ore have been proven to exist in the Province of Quebec, although there are widespread indications of iron, but it is possible that extensive beds of iron ore may yet be discovered or that some of the known deposits, now regarded as doubtful, may prove to be of great value.

There is some reason to believe that there may be extensive iron ore deposits along the Gatineau River in Hull Township, Ottawa County, Quebec, within a few miles of the City of Ottawa. Many years ago three mines were opened in what is known as the Hull Range, viz., the Forsyth, Baldwin and Lawless. From the Forsyth mine, 8,000 tons of ore were shipped to Cleveland, Ohio, between 1854 and 1858, averaging, it is said, over 60 per cent. in metallic ore. The ore was magnetite, low in phosphorus and sulphur. Shipments ceased because supplies of ore more conveniently situated for transportation to the Cleveland market, were discovered. In 1867 a charcoal blast furnace was started in the vicinity of the mine, but was only in blast for about a year. At the Baldwin and Lawless mines very little development work has ever been done. Mr. Fritz Cirkel, M.E., of the Dominion Department of Mines, who recently made a report covering 147 pages on the deposits along the Ottawa and Gatineau Rivers, thinks it probable that there may be a large body or ore in the Forsyth, and says that while the Baldwin deposits seem to be more irregular and to consist largely of pockets, the quantity of ore exposed, although scattered, is of sufficient importance to justify mining operations on a large scale. Of the Lawless mine he says that no solid ore bed of any extent can be seen on the surface, but there are some pockets of very good quality. He states that the principal constituent of the ores of the Hull Iron Range is magnetite, intermixed at some places with hematite and associated with a gangue material, and that they contain from 53 per cent. up to about 67 per cent. of metallic iron, the highest percentages being obtained from magnetite ores free from hematite. The ores are very low in phosphorus. Sulphur is present in the form of pyrites and is in some cases confined only to the edges of the deposit. Mr. Cirkel believes that in actual mining these parts of the deposits can be passed by or the pyrites can be eliminated by cobbing. The iron bearing area is estimated as having approximately a length of 6,800 feet, while the width ranges from 40 feet to 100 feet. The deposits are numerous in the eastern portion of the range, but thin out in the extreme western portions. In the Township of Templeton near the boundary of Hull Township, is the Haycock mine, where in April, 1873, rather extensive mining operations were begun and continued for several years. No work has been done for over thirty years. Very little information is obtainable regarding the old mining operations. Mr. Cirkel reports that all the deposits he examined so far as surface indications go are of limited extent, but he thinks it possible that large ore bodies may be found in the neighbourhood. The Haycock ore is hematite, having sometimes an admixture of magnetite, and samples taken from a number of pits indicate that it has a high percentage of iron, being low in both phosphorus and sulphur, but high in titanic acid. There are several other iron ore deposits in Templeton Township, which appear to be of much the same character as the Haycock. Mr. Cirkel reports that there are many small outcrops of both magnetite and hematite in the different townships bordering on the Gatineau River, but the value of the deposits cannot be determined without development work.

The Bristol iron mines are in the Township of Bristol, County of Pontiac, about two miles north of the Ottawa River and a little over four miles from Wyman station on the Canadian Pacific Railway. Between 1885 and 1888 about 12,000 tons of magnetite iron ore are said to have been shipped, principally to Pennsylvania furnaces, but no mining has been done for twenty-one years. Samples of ore analyzed show that it is high in metallic iron, very low in phosphorus, somewhat high in sulphur, and contains a small percentage of titanic acid. Mr. Cirkel says that the ore, though generally called magnetite, is really a mixture of crystalline magnetite and hematite of varying proportions. Regarding the sulphur, he says: "In the Hull Iron Range, iron pyrites is met with mostly in a coarse form in certain portions of the ore bodies, and these can easily be separated by hand from the pure ore. The distribution of iron pyrites throughout certain masses of the ore bodies at the Bristol mines, in the form of fine irregular veins and disseminations, renders mechanical cleaving impossible, consequently such ores, which from outside appearance contain too much pyrites, must be submitted to a roasting process, in order to keep the contents of sulphur in the smelting ore below the admissible limit." However, Mr. John Birkenbine, M.E., who made a report on the Bristol mine in 1888, said that while the large quantity of pyrites in the upper levels of the mine necessitated roasting the ore, the pyrites had become so much diminished in the lower workings that roasting was no longer necessary.

The Bristol iron-bearing formation has an approximate length of about 1,500 feet and an approximate width of 500 feet. "As to the extension of the ore bodies in depth," says Mr. Cirkel, "it is known that in the main shaft a depth of 200 feet has been reached and that the ore there is still continuous. In another place a depth of seventy-five feet was reached and, according to the statement of the foreman who worked this pit, the bottom is still in good ore."

The Chats waterfall of the Ottawa River is within a few miles of the Bristol mine and electric power could be developed at very low cost.

There are a number of deposits of iron ore throughout the County of Pontiac. Some of them are evidently poor in quality and limited in extent. Others make a better showing, but only development work would prove whether they are of any value or not.

On Calumet Island, in the Ottawa River, both magnetite and hematite ores have been found, but no development work has been done and the quantity of ore is uncertain. An analysis of hematite ore showed it to be very low in both phosphorus and sulphur, but it contained a small percentage of titanic acid.

There are large supplies of limestone within easy reach of the iron ore deposits along both the Gatineau and the Ottawa Rivers, and there are a number of waterfalls not far distant, from which electric power could be obtained. It has been suggested that these ores might be smelted by electricity.

In Grenville Township of Argenteuil County, about half way between the cities of Montreal and Ottawa, are iron deposits which have been talked of for years, but little development work has been done. There are a number of pockets of magnetite, but no large bodies of ore have been discovered. Other iron ore deposits which have been favourably mentioned in government geological reports, but which may be described as "not proven" are the St. Jerome mine in Terrebonne; the Boniface mine in Shawenegan; the Leeds mine in Leeds and the Sherbrooke mine in Ascot.

It is estimated that there are many millions of tons of iron sands containing a high percentage of iron along the north shore of the St. Lawrence, at Moisie, Mingan, Natashkwan and other places. These sands could be briquetted for use in the blast furnace, but unfortunately they contain a high percentage of titanium. Titanium while not injurious to iron, as sulphur and phosphorus are, causes trouble in the furnace when present in quantity. A very small percentage may be handled without much trouble and it improves the quality of the iron. There are a number of deposits of bog iron ore in the St. Lawrence Valley remarkably free from sulphur and phosphorus and containing so small a percentage of titanium that it may be regarded as advantageous rather than injurious. Dr. Eugene Haanel, director of the Dominion Department of Mines, says of these bog ores: "The origin of these deposits is interesting since they are being continually found at the present time, and it is possible to obtain ore which has been deposited during the last ten or twenty years. The rocks are highly ferruginous and the iron is dissolved from them by the action of the rain-water containing organic acids resulting from decayed vegetation. The iron thus dissolved is transformed into salts of the protoxide. These mineralized waters stream down from the hills into the valleys and inland lakes, where the protoxide salts carried by the decomposed vegetation float on the surface of the water and are acted upon by the oxygen of the atmosphere; which converts the protoxide into the insoluble peroxide of iron. By a natural accretionary process, the iron oxides form into cakes of ore about 7 inches in diameter; then they drop to the bottom of the lake. This evolutionary process is so rapid that some of the lake bed deposits which have been worked out, are found after a rest of five years to have grown sufficiently to enable the owners to work them by dredge mining for ten years continuously on a commercial scale."

The use of these bog iron ores by the Canadian Iron Corporation in its furnaces at Radnor Forges and Drummondville has already been referred to.

The Provinces of Quebec and Ontario, south of the Height of Land, are entirely destitute of coal. Lignite is known to exist between the Height of Land and James Bay, and it is possible that good coal may yet be found in some part of that great country. Recent newspaper despatches have stated very positively that good coal has been found under the lignite in the vicinity of the Mattagami River, about 70 miles from Cochrane, the terminus of the Temiskaming & Northern Ontario Railway, but such statements will not be taken seriously unless supported by the report of the exploring party which the Ontario Government has sent to investigate.

For ordinary domestic and manufacturing purposes the Province of Quebec gets its supplies of coal largely from Nova Scotia, although considerable quantities of coal are imported from the United States. Whether it would be possible to use Nova Scotia coal for iron making in Quebec Province is doubtful. If abundant supplies of iron ore could be laid down cheaply at Montreal and arrangements could be made with one of the Nova Scotia coal companies to supply coal at the mines at as low a price as the Dominion Iron & Steel Company secured its coal from the Dominion Coal Company, the cost of transportation to Montreal would probably not preclude its use for smelting purposes. There is deep water all the way and very large boats could be used for the transportation of the coal. It is not probable that coal could be obtained at so low a price from any of the existing coal companies, but it is possible that an iron and steel company with blast furnaces in Montreal might buy a Nova Scotia coal mine and so secure coal at the cost of mining and transportation. There are abundant supplies of limestone near at hand. The Drummond iron mine of the Canada Iron Corporation, near Bathurst, in Gloucester County, New Brunswick, is considerably nearer to Montreal than the iron mines of Michigan and Minnesota are to the blast furnaces in Buffalo and Hamilton. If the iron ore deposits along the Ottawa and Gatineau Rivers should prove to be important they could be economically transported to Montreal.

It has been announced that the Government will undertake the construction of the Montreal, Ottawa and Georgian Bay Canal as soon as the Grand Trunk Pacific Railway is completed, and as the leaders of both political parties have expressed themselves as in favour of the project there is little doubt that the work will eventually be carried out. In considering the present conditions of Canadian iron and steel industries it cannot be regarded as a factor, but in any estimate of the future it must be taken into account. When that canal is completed Montreal will be as near to all the iron ore ports of Lake Superior as Hamilton now is. Key Harbor, on Georgian Bay, the port of shipment of the Moose Mountain mines is within a few miles of the mouth of French River, where this short water route begins, a distance of 440 miles from Montreal.

Montreal is the commercial metropolis of the Dominion and it has many manufacturing industries using iron and steel as raw materials. It is the headquarters of the Canadian Pacific, the Grand Trunk and the Grand Trunk Pacific Railways, and the most important workshops of those companies will probably always be located there, so that the local demand for iron and steel will always be large. It is the meeting place of lake and ocean navigation. Situated 960 miles from the ocean, it has the unique position of being both an inland city and a port for ocean vessels, which gives it certain advantages as a distributing point over any other city in America during the season of navigation on the Great Lakes and the St. Lawrence River.

Under ordinary conditions it is much more economical to manufacture iron near the raw materials, but sometimes the advantage of being close to a large consuming centre partly offsets the disadvantage of being somewhat distant from all the raw materials. Thus the blast furnaces of Chicago get all their raw materials from a distance, Connellsville coke being carried 600 miles to that city, as shown in my last article. Professor Smith, of the University of Pennsylvania says regarding the economic location of blast furnaces: "In the making of iron it is usually necessary for the fuel or the ore to be transported to some common meeting place, and in the working out of the problem of transportation the location of the iron industry has usually responded to the motto that 'the ore goes to the fuel,' an example of this being the great movement of Lake Superior ores to the Pennsylvania coal fields. It is not, however, a maxim of absolute sway. The question is rather complex and is to be answered by weighing various freight factors involved in getting the

ore and the fuel to the furnace and the finished product to the market. It is, therefore, a triangular problem, and it sometimes works out to the moving of the fuel rather than of the ore. Examples of this are afforded by the present industry on Lake Champlain, and in Northern New Jersey. Here are ore fields of excellent character; in both fields iron is being made with coke from Western Pennsylvania. The reason they can afford to break the maxim and carry the fuel to the ore is found by noting the disposition of the finished product. It goes to New England and the East, and the fuel is therefore moving toward the final market of the iron.

Coal carried from Nova Scotia to Montreal would be "moving toward the final market of the iron," and this is true also of the United States coal or coke that goes to the Ontario furnaces at Hamilton, Midland, Sault Ste. Marie, and Port Arthur.

One advantage of having iron and steel works close to the market is that in case of a rush order delivery can be made in shorter time, and this is sometimes a factor in securing business.

All the blast furnaces in Ontario are distant from coal mines. Nova Scotia coal is sent in limited quantities to some of the most eastern counties of Ontario for domestic and ordinary manufacturing purposes, but the cost of transportation prevents it going farther west, and consequently almost all the coal used in Ontario is imported from the United States. Under present conditions the use of Nova Scotia coal for iron making could not be considered in any part of Ontario. If the Canada Iron Corporation owned a Nova Scotia coal mine it is possible that it might take coal as far as its blast furnaces at Midland, Ont., after the projected Montreal, Ottawa and Georgian Bay Canal is completed. It is not probable that Nova Scotia coal could be economically used for smelting purposes farther west than Georgian Bay ports, although Mr. Alex. Dick, the general sales-manager of the Dominion Coal Company, told me that if that canal were constructed so that large coal barges could go through from Cape Breton without breaking bulk, he believed they could sell large quantities of coal for domestic and ordinary manufacturing purposes as far west as Fort William. It may be noted that some of the iron ores of Northwestern Ontario are rather too high in sulphur for use with Nova Scotia coal. The blast furnaces at Port Arthur and Sault Ste. Marie use West Virginia coal, which has a very small percentage of sulphur. The Lake Superior Corporation recently purchased a coal mine in West Virginia in order to be in an independent position. The rail haul is between 330 and 340 miles from the West Virginian mines to Toledo on Lake Erie from which the coal can be shipped by water to the blast furnaces of the company at Sault Ste. Marie, Ont.

The blast furnaces of the Lake Superior Corporation at the Sault and the Atikokan Iron Company at Port Arthur, are distant from their fuel supply, but they have the advantage of being much closer to the great Northwest than furnaces farther east.

Midland blast furnaces at present use Connellsville coke, which has an all-rail haul of about 535 miles. When the coke ovens now projected by the Canada Iron Corporation at Midland are completed, coal will be imported instead of coke, and as it can be shipped a great part of the way by water the rail haul will be considerably reduced. The rail haul from Connellsville, Pa., to the blast furnaces of the Hamilton Steel & Iron Company is about 388 miles. Hamilton manufacturing industries consume large quantities of both iron and steel and it is the centre of a district in which are a number of manufacturing towns, so that the fuel meets the iron ore where the finished product is sold.

There do not appear to be any iron ore deposits in Southwestern Ontario worth mentioning except the bog ores of Norfolk and Oxford Counties. At Normandale, in Norfolk County, Joseph Van Norman successfully operated from 1820 to 1847 a charcoal blast furnace using local bog iron ore. Small quantities of the Oxford County bog ores have been smelted at the Hamilton furnaces. Whether the bog ores of Ontario grow, as the Quebec deposits are reported to do, I am unable to state.

Anyone reading the Dominion Government geological reports published some years ago and the Report of the Royal Commission upon the Mineral Resources of Ontario, published in 1890, would be likely to suppose that there were a number of very extensive ore beds in Eastern Ontario containing high-grade ore. Witnesses before the Royal Commission were quite enthusiastic about the extent and value of some of these deposits, but there is reason to believe that exaggerated views prevailed at that time. Iron ore is found over wide areas in Frontenac, Lanark, Renfrew, Leeds, Hastings, Peterborough, and Haliburton counties, but most of the deposits are now believed to be merely pockets. Prospectors have been too ready to assume that when several deposits of ore are found in line with each other they must be outcrops of the same ore bed. There appear to be a great number of separate deposits, many of them containing considerable quantities of ore, but as yet no very extensive body of good ore has been proven to exist. Magnetites are more common than hematites, but about 150,000 tons of hematite ores are said to have been taken out of Eastern Ontario mines. Bog iron ore is reported to exist in Lanark County.

Considerable quantities of both magnetite and hematite iron ore were shipped to the United States many years ago, and very favourable reports of the quality of some of the ores were received from the smelting companies, but nearly all of these mines were abandoned long ago, and very little development work has been done in recent years. It is difficult now to ascertain what was proven by these old-time mining operations. It is certain that in some cases the analyses showed the ores to be high in iron, low in both phosphorus and sulphur, and free from titanium, but in other cases the ores were of low grade and contained considerable quantities of sulphur, phosphorus, or titanium. Some of the deposits seem to be irregular in quality, inferior ore being found in close proximity to first-class ore. It would probably be correct to say that in general the ores of Eastern Ontario have a high percentage of iron, are low in phosphorus and titanium, and rather high in sulphur, but that there are exceptions. In some localities there are considerable quantities of magnetite containing a high percentage of titanium.

The Ontario Government for some years offered a bounty of one dollar per ton for pig iron made from Ontario ore, and the Dominion Government iron bounties for a number of years discriminated to the extent of one dollar per ton in favour of pig iron smelted from Canadian ore. But these inducements brought out very little Eastern Ontario ore. However, it would be a mistake to assume too readily that no ore deposits of great value will ever be found in Eastern Ontario. It is probable that thousands of tons of good ore will be taken from some of the mines already opened, and development work in some of the localities yet unworked may reveal valuable ore

beds. The mine of the Canada Iron Corporation near Eganville in Renfrew County has been already referred to. Considerable quantities of ore were shipped to the United States from the Wilbur Mine in Renfrew County many years ago, and ore from this mine has been used in Canadian blast furnaces in recent years, going as far west as the works of the Lake Superior Corporation at Sault Ste. Marie, Ont. The ore is magnetic, low in both phosphorus and sulphur and is suitable for making Bessemer pig iron. This mine has recently been acquired by a New York corporation, and it is stated that active development work is to be undertaken. There has been some talk of establishing a blast furnace at Kingston to use this ore.

Farther north in Ontario ore has been found at many points from Lakes Temagami and Temiskaming to Sault Ste. Marie, but no important iron ore bodies have been proven to exist in this region east of Sudbury. About 25 miles north of Sudbury in the Township of Hutton is the much talked of Moose Mountain iron range, which promises to yield large quantities of iron ore. The company owning the deposits has been incorporated under the name of Moose Mountain, Limited. J. W. Gates, the well-known New York capitalist, is president, and Donald D. Mann of Mackenzie & Mann is largely interested in the company, which owns forty-six hundred acres of land. There are said to be eleven well-defined bodies of iron ore on the property, which are numbered. No. 1, No. 3, and No. 4 are said to be high grade ore, while the others, so far as known, are low grade. The shipping point is Key Harbor, Georgian Bay, about eighty miles south of the mine, and transportation facilities are provided by the Canadian Northern Railway. The harbour has 24 feet of water, is well sheltered, and the dock equipment includes a thoroughly modern transfer loading plant.

I am indebted to Mr. C. E. Harrmann, assistant to the president of Moose Mountain, Limited, for the following statement:

"Not enough exploration work has been done on the property to permit making any accurate estimate of the tonnage or grade of ore available, except in the case of the Number One deposit. Diamond drill exploration on this deposit has developed over one million tons of concentrates of the present guaranteed grade, 54.50 per cent. metallic iron when dried at 212 degrees Fahr. The company is operating an open pit on this outcrop, and shipped between twenty-five and thirty thousand tons of concentrates during 1909. This ore was crushed to one inch maximum and magnetically cobbed, the average analysis for the season being, at 212 degrees Fahr.:

Silica	12.78	Manganese	.09
Iron	55.77	Lime	3.77
Phos.	.107	Magnesia	3.52
Alumina	1.58	Sulphur	.074
Loss by ignition			none
Moisture in natural ore			.77

"The plant and machinery used during the season of 1909 was largely of an experimental nature, the season's results demonstrated that the process used was entirely successful, and at the close of the year the company adopted a wider plan of operation. Construction work was carried on during the winter and a new mill, electrically operated and up to the minute in every particular, is nearing completion, and is, as far as is known to us, the only magnetic concentrating plant in Canada. Approximately one hundred thousand tons of concentrates will be shipped to the United States during the present season, according to program.

"The company's efforts have been concentrated upon opening the Number One deposit, and according to present status of the work the end of this season will see the mine on a good round tonnage basis. As soon as this is accomplished the other deposits of high grade ore will be attacked, and meanwhile investigations and experiments are being carried out with the view of utilizing the lower grade of ores."

Shortly after the discovery of the Moose Mountain iron range was announced, the Toronto newspapers contained articles intimating that the interests in control proposed to establish great iron and steel works at Ashbridge Bay, Toronto, using Moose Mountain ore. Toronto is not quite so favourably situated as Hamilton for assembling the raw materials of iron-making. Hamilton has limestone close at hand and there is natural gas in the neighbourhood, which is piped to the city. The railway charges for transportation of coal or coke from the United States are ten cents per ton greater to Toronto than to Hamilton. The iron ores of Eastern Ontario are nearer to Toronto, but the Moose Mountain Mines, the Atikokan range, the ores of Michipicoten, and all the great Michigan and Minnesota mines are about forty miles nearer to Hamilton than to Toronto. Large quantities of iron and steel are consumed in both Hamilton and Toronto, and the two cities have almost equal advantages for the shipment of iron to other manufacturing towns in Ontario. When the Ottawa and Georgian Bay Canal is opened the Moose Mountain mines will be nearer to Montreal than to either Hamilton or Toronto by the water route.

The Atikokan iron range on the line of the Canadian Northern Railway, about 130 miles from Port Arthur, was described in my second article. It seems likely to afford an ample supply of ore for the blast furnace of the Atikokan Iron Company at Port Arthur. The United States Steel Corporation is said to have purchased another promising magnetite deposit, running low in phosphorus and sulphur, a few miles west of Atikokan.

The Helen iron mine of the Lake Superior Corporation, about eleven miles from Michipicoten harbour, has already been described. It is undoubtedly an immense ore body, and great quantities of ore have already been taken out. There is reason to believe that a number of other valuable ore bodies will be found in the great region north of Lake Huron and Lake Superior, and south of the Height of Land, but exploration and development work is expensive. It is said that the great American iron and steel companies, which have ample capital for such work, are beginning to explore this region. If the United States Steel Corporation should get control of large iron ore deposits in Ontario it might seriously interfere with the development of the Ontario iron and steel industry. It would seem worth while for the Ontario Government to expend a large amount of money in exploration work, and to adopt measures which would prevent iron ore properties passing under American control.

The country north of the Height of Land is almost unexplored. It is claimed that extensive iron ore beds have been found near the Mattagami River, but until further investigation no opinion can be formed of their value.

It is unfortunate that Ontario blast furnaces are

dependent upon the United States for supplies of coal or coke. It has been suggested that the United States Congress may at some future time levy an export tax on coal. However, the United States constitution provides that "no tax or duty shall be laid on articles exported from any State." An amendment to the United States constitution must be first approved by a two-thirds vote of both Houses of Congress, and afterward ratified by the Legislatures of three-fourths of the States or by conventions in three-fourths of the States.

Charcoal pig iron is for certain purposes much superior to coke pig iron, and Ontario ought to be able to produce sufficient charcoal to supply a number of furnaces. Yet it has been difficult in the past to get supplies for the one charcoal furnace of the province, which is located near Deseronto. Owing to the scarcity of charcoal it was converted into a coke furnace, but since it came into the possession of the Standard Chemical Company, which is a large producer of charcoal, the use of charcoal has been resumed. When the Canada Iron Furnace Company, now included in the Canada Iron Corporation, selected Midland as a blast furnace site it was at first proposed to use charcoal, but the owners of timber suitable for the purpose demanded such high prices that the use of coke as fuel was decided upon.

There are large areas of Ontario unsuitable for agriculture, but well adapted for growing timber. It would be well for the Ontario Government to make enquiry as to the best means of assuring cheap supplies of charcoal in the future.

A series of experiments were conducted at Sault Ste. Marie in 1905-6, under the direction of the Dominion Department of Mines, with the object of establishing the feasibility of electrical smelting of Canadian magnetic iron ores. Dr. Eugene Haanel, Director of Mines, was well satisfied with the results. Three young Swedish engineers, Assar Gionwall, Axel Lindblad, and Otto Stalhane, stimulated, it is said, by the results of the Sault Ste. Marie experiments, undertook to solve the problem of designing and constructing a commercial electric smelting furnace. Arrangements were made with the largest iron manufacturers in Sweden to carry on smelting experiments at the Domnarfvet iron works. After two years of experimenting a furnace was evolved which they are satisfied can be economically used in practice. In December, 1908, Dr. Eugene Haanel went to Sweden to witness the first practical test, and after watching the working of the furnace in a twelve days' trial run, he was most favourably impressed, and he has published a very interesting report. The fuel used was coke, but charcoal may be used. If Dr. Haanel's expectations should be realized, iron ores may yet be extensively smelted in Ontario and Quebec by the thermo-electric process, both provinces having many waterfalls from which electric power can be generated. It is claimed that in the electric process the quantity of coke or charcoal consumed is so small that the cost of fuel is greatly reduced, and that sulphur can be much more successfully eliminated than in ordinary blast furnace practice. That iron of very high quality can be produced by this process there is no doubt. Whether the electric furnace can ever successfully compete with the ordinary blast furnace using coke as fuel is a question for the future to decide.

So little is known of the country surrounding Hudson Bay that no one can say what may be discovered there. It is possible that at some future time coal, iron and limestone may be found in locations from which they can be conveniently carried to Fort Churchill or Port Nelson for smelting. It is not probable that the Hudson Bay route to Europe will ever prove a great success, as Hudson Strait, at the far north, is blocked with ice for a great part of the year, but the great bay itself is open throughout the year and the harbours of Fort Churchill and Port Nelson are open for navigation for almost as long a period as Montreal is. There is no doubt that the vast prairie country will eventually have a population of many millions, and there will be a great demand for iron and steel. If raw materials could be cheaply assembled at one of the Hudson Bay ports this great market might be more accessible to works located there than to the works in Eastern Canada. However, this is not a problem for the present generation to consider.

Alberta has very extensive coal areas, lignite, bituminous and anthracite coal being already mined in considerable quantities. Much of the coal is unsuited for the manufacture of blast furnace coke, but the quality improves as the mountains are approached, and some of the bituminous and anthracite coal near the boundary of British Columbia will no doubt be suitable for iron making. So little exploration work has been done that nothing definite can be said about iron ores. The rule that iron ore can be carried a considerable distance to the coal when there is a market near at hand for the finished iron will apply in the west as well as in the east.

British Columbia has probably greater areas of first class coal than any other province of the Dominion. The mines in Vancouver Island and in the Crow's Nest Pass are well known to Canadians in general. The report of the Mines Department states that mines are being opened in various localities on the western slope of the Rocky Mountains, in the Nicola Valley, on the Thompson River, on the Queen Charlotte Islands, and in the valleys of the Skeena and Telkwa in the north. Other discoveries of coal will probably be made.

As there has in the past been no demand for iron ore in British Columbia very little exploration work has been done. The Mines Department reports that iron ore deposits of more or less value have been discovered in the following localities: Texada Island, between Vancouver Island and the mainland; West Redonda Island, in the Gulf of Georgia; Queen Charlotte Islands, Klaanch River, Quinsam River, Sarita River, Head Bay, Gordon River, Sechart, Kennedy Lake and Quatsino Sound on Vancouver Island; at Rivers and Knight Inlets on the mainland coast; Cherry Bluff, near Kamloops; Fort George, and in several localities of the mainland districts of Similkameen and Cariboo. As regards the value of these deposits no definite statement can be made until more development work has been done. The Puget Sound Iron Company, which has a property of 2,700 acres on the south-west side of Texada Island, has shipped small quantities of ore to Irondale, Washington, where it has been smelted with a mixture of one-ninth to three-tenths of bog ore, making an excellent foundry pig, which, according to the report of the Mines Department, was used by the Union Iron Works of San Francisco in the construction of the United States warships Olympia, Monterey, Charleston, and Oregon.

If iron and steel works on a large scale were located either on the mainland coast of British Columbia or on the islands they would be well situated for sending

the finished products to the markets of the Pacific, including the west coast of South America, Japan, China, Australia, and even to the Pacific coast cities of the United States, which are not favourably located for assembling the raw materials of iron making.

The building of steel steamships will probably become an important British Columbia industry, and some of the warships of the Canadian navy will no doubt be built at Pacific coast shipyards.

In the ten years ending 1908, royalty to the extent of $3,615,381 was collected on the gold production of Yukon Territory.

ELECTROLYTIC CYANIDATION AND AMALGAMATION.

BY ELMER ELLSWORTH CAREY.*

Inventions and processes are frequently announced many years before the world is ready for them. The electrolytic cyanide process was described by Rae in 1867, but to-day only one part of that process—electro-deposition—is in use. The electrolytic system of separating and refining metals is now rapidly superseding all other metallurgical systems, and the electrochemical system will before long be used extensively in the metallurgy of gold. By the use of electricity the percentage of gold won will be increased, the cost of extraction diminished, and the area of mining operations greatly enlarged. As soon as the various colleges, institutes, technical schools, etc., teach the principles of electrochemical metallurgy, important modifications and changes will be made in milling operations. As cyanidation made slow progress till a new generation of engineers had been trained in the use of the chemical system, so the electrochemical metallurgical methods will languish till the schools have supplied the necessary electrochemical engineers.

It has been known theoretically for forty years that the amalgamating action of mercury and the energy of the cyanide solution could be increased by the introduction of certain electrochemical conditions, but many difficulties had to be overcome before this knowledge could be used in a practical manner. Within the last ten years the science of electrochemistry has been placed on a firm foundation, and the troubles of the early inventors have been surmounted. Low voltage generators are now manufactured that produce the required current at an insignificant cost; by the use of Acheson graphite, all anode trouble disappears; and the time of treatment has been reduced to a few hours, while in some systems the values pass into solution and are deposited simultaneously.

Metallurgical science took a great step forward when the chemical (cyanide) system was introduced, and the next important step will be the adoption of the electrochemical system. Many troubles, obstacles and difficulties of cyanidation disappear when electrochemical conditions are introduced; values which ordinarily are refractory readily pass into the solution; a weaker solution than usual may be used; the solution is constantly regenerated; the loss of cyanide is reduced; the values are automatically recovered in the form of amalgam; the refining processes, with their attendant losses, are unnecessary, and the cost of installation greatly reduced.

In "The Mining World," Chicago, January 23, 1909, may be found a description of the Parks electro-cyanide process. The process here described is extremely simple, effective and inexpensive, and has been found successful with ores which are not amenable to the usual cyanide treatment. In the works on cyanide practice by Bosqui, Wilson, Smart and others, will be found descriptions of other systems of electro-cyanidation, all of which have similar basic features, differing only in detail, modes of construction, etc. Some years ago electro-cyanidation was successfully used for several months at the Delamar Mine in Idaho, and a description of the process there used will be found in Bosqui's work.

The recovery of values from a cyanide solution (after the usual leaching process) by electro-deposition has proved successful in many mills in South Africa; the Siemans and Halske process of electro-precipitation was introduced several years ago on the Rand, and despite the primitive apparatus used, the high cost of installation, and the five per cent. royalty, many companies have adopted the process.

To-day the special process in question is obsolete, as far better methods are known; Acheson graphite is much better for anodes than the clumsy iron anodes used in the German system, and amalgam plates can now be used instead of the lead cathodes. With the introduction of discoveries, methods, machinery and accessories which have been placed at our disposal by American inventors and investigators in the electrochemical field, the time has now arrived when the art of cyanidation can be completely revolutionized. Some of the advantages that may be expected from the improved system are mentioned in an article on "Electrochemical Amalgamation and Cyanidation" in the Engineering Magazine, for December, 1909, as follows:

"Turning to electrochemical lixiviation, the claim is made that under electrochemical conditions the cyanide solution is much more active than usual; values pass into the solution which are lost in the ordinary systems; the time of treatment is reduced and the extraction increased, while there is a decrease in the operating cost; precipitation by electro-deposition goes on simultaneously with the leaching process and the usual troubles are eliminated; a molecule of cyanogen after taking up a particle of gold, is released as nascent cyanogen, having greatly increased affinity for gold and silver. The solution is constantly regenerated, the loss of cyanogen being negligible. The larger particles of gold are amalgamated directly without passing into the solution. In electro-cyanidation the pulp and solution are agitated in a shallow tank having the bottom covered with quicksilver (cathode); revolving stirrers cause the pulp to travel with a circular motion over the quicksilver for an hour or two; this is equivalent to passing the pulp over several miles of mercury surface. During this period the values are amalgamated directly, or pass into the solution and are precipitated by electrolysis, the extraction averaging 97 per cent. All ores, so far as known, are capable of successful treatment by means of electro-cyanidation."

Regarding electro-amalgamation, it may be said that

* Member American Electrochemical Society, San Jose, California, U.S.A.

experimental work relating to electrochemical amalgamation began in 1859, the first patent being issued to Henry Brevoost, of San Francisco; some 75 patents for various electro-amalgamating devices have been issued by the United States patent office, but only within the last three years have machines been constructed which meet the requirements of mining men. The various engineering difficulties have been overcome and an electro-amalgamating device is now constructed which is very simple, inexpensive, has large capacity, is easy to operate, skilled attendance not being necessary, and which extracts all values not encased, regardless of refractory elements which may be present in the gangue. Such a device works equally well with mill pulp or screened placer material; in placer operations all rusty, coated and black sand values, as well as platinum, are amalgamated; fine, float and beach gold is readily amalgamated in the electrolytic device. Those who wish an authoritative statement as to the value and scope of electrochemical amalgamation are referred to a paper by Warnford Lock mentioned below, and also to the patent issued to Sir William Crookes.

Those who wish further to investigate electro-cyanidation are referred to the following:

"Mining World," Chicago, January 23, 1909; article by John R. Parks, E.M.

"Engineering Magazine," New York, December, 1909; article, "Electrochemical Amalgamation and Cyanidation."

A SLOCAN, B.C., PIONEER AND HIS MINING PROPERTIES.

By E. Jacobs.

The death of George W. Hughes, which took place at Portland, Oregon, U.S.A., on June 14, brings to mind remembrance of the active and very useful part he took in the development of the Slocan mining district of British Columbia, particularly in the nineties, in which Slocan mines made large production of silver and lead, and some of them paid considerable amounts of money in the shape of dividends to their then fortunate owners.

The late Mr. Hughes prior to going to the Slocan in 1892 was engaged in railway construction work in northeastern Washington and contiguous parts of the northwestern United States. He took to British Columbia a pack train of some 40 mules, to pack supplies in to the Slocan mines and ore out to Nakusp or Kaslo, for shipment thence to the United States. Becoming impressed with the great ore-producing capabilities of the Slocan, he took a prominent part in road-building, so that it might be practicable to transport larger quantities of ore to the waterways of the country than could well be done by pack train. The wagon road from the heart of the Slocan to Kaslo, on Kootenay Lake, was accordingly built, and this gave the district an outlet for its mineral products to the east, in addition to that to Nakusp, to the westward on Arrow Lake, Columbia River, provided about the same time. Later, railways were constructed from both those places to Sandon, thereby giving the numerous producing mines of the Slocan competing routes for the transportation of ore to smelters, and for getting in supplies.

After adequate transportation facilities had thus been provided, Mr. Hughes turned his attention to practical mining and for some years managed one or other of several of the mines of the Slocan. Later he acquired large interests in well-known properties, operating them successfully and thereby realizing a competence. Chief among these were the Sunset and Lucky Jim mines, respectively, both of which were important producers of ore, the former of high-grade silver-lead and the latter of zinc. Other properties in which Mr. Hughes became interested as owner or part owner were the Bell, in Jackson Basin; and the Mountain Chief, Apex, and Mammoth, near New Denver. The passing away of the late owner of these mining interests would appear to make the present an opportune time to give some information relative to these properties in the development of which he took so prominent a part, and incidentally contributed to the material progress of the Slocan district.

The Sunset Group.

The Sunset group of six mineral claims is situated on the divide between Jackson Basin and Cody Creek. The group embraces the Sunset, Trade Dollar, No. 3 Fraction, Nabob, Cashier, and Bell. The last-mentioned was not one of the original Sunset group, but was acquired later than the others; it is on the Jackson Basin side of the mountain and is a zinc more than a silver-lead mine.

From a return showing the quantity and value of the total production of the Sunset group, the following figures have been taken: Total output of ore, 2,663 net tons; average metal contents, 132.23 ounces silver per ton and 72.8 per cent. lead; total value of ore produced, $263,358 gross; smelter, freight and treatment charges per ton, $14.91; net value of ore per ton, $83.95.

The first ore met with in the Sunset was on the floor of No. 1 tunnel and the shoot continued down to No. 5, which was the lowest level driven on the claim. This was on the Jackson Basin side of the divide. The best results were obtained in 1898-1899; after those years not nearly so much ore was shipped. The greatest bulk of the ore was taken from Nos. 2 and 3 levels. In the Trade Dollar, No. 1 level was practically non-productive. No. 4 proved a barren level, while No. 5 produced only a little ore. Nos. 6 and 7 were very productive especially the latter. The ore shoot in No. 7 was about three times as long as in No. 6; it has been stoped clear through from No. 7 to No. 6. There is not any connection between Nos. 6 and 5, but there are raises from 5 to 4, 4 to 3, and 3 to 2, respectively. Much of the known ore above No. 7 has been stoped out up to No. 1. The indications are that No. 8 will contain more ore than No. 7 did.

The Sunset mine was closed in the years 1903-1904. In 1905 Mr. A. J. Becker took charge as manager and resumed shipping ore, which he continued until October, 1908. On January 1, 1909, owing to the serious illness of Mr. Hughes, operations were discontinued for the time, and the mine was closed until the following September, by which time it had been conditionally purchased by the Sunset Silver Lead & Zinc Mines Company, incorporated under the laws of the State of Washington. This company has an authorized capital of $1,000,000 in shares of the par value of $1. The following constitute its board of directors: R. V. Montague, president; George Robertson, vice-president, and E. R. Locke, secretary-treasurer (all of Mexico, Missouri); A. J. Becker, of Kaslo, B.C., general manager, and J. H. Lothrop, of Spokane, Washington, assistant secretary and treasurer. Beside the Sunset group and Bell, the company acquired the late Mr. Hughes' interests in the New Denver mineral claims already mentioned. Other interests held in those claims are two-thirds in the Mountain Chief by A. W. McCune and associates, and a controlling interest in the Mammoth by Finch & Campbell, of Spokane, Washington.

Immediately after the organization of the Sunset Company and its arrangement to acquire the property, a contract was let for driving No. 8 tunnel on the Cody side of the mountain, with the object of cutting the vein at a lower level and opening up new ground for ore stoping. It was calculated that this adit would have to be driven between 500 and 600 feet to reach the vein at a vertical depth of 246 feet below No. 7 level. The breast of this drive is now 520 feet from the portal, so it will not be long until the vein shall be reached. Thereafter drifting for about 500 feet will be necessary to reach the ore shoot which proved so productive in No. 7, and which, it is believed, will prove to be still longer on No. 8 level. There are good indications that another shoot of ore will be found in the vein between the point at which the cross-cut will enter it and the calculated position of the continuation of the ore body worked in No. 7. The reason for driving No. 8 from its chosen starting point was that in doing so an exit from the lowest level of the mine clear of snowslides would be thereby provided, and danger to men going to and fro would thus be avoided. In this connection it should be remembered that during nearly half the year there is much snow on Slocan mountains, even where the altitude is only about 6,000 feet, as in the case of the Sunset group, so that it is imperative, for considerations of safety to the miners, portals of tunnels shall if possible be out of the path of the snowslides which come down each recurring season.

The first ore shipped from the Sunset was rawhided over the Jackson Basin trail down to the Kaslo & Slocan Railway at Whitewater, a distance of seven miles. Later, after connection had been made between the Trade Dollar, on the Cody side of the divide, and the Sunset workings on the Jackson Basin side, the ore was sent down to the railway terminus at Cody, distant only two miles, and at an elevation about 2,000 feet lower than that of the Trade Dollar workings. The K. & S. Railway has not been operated beyond McGuigan, which is 10 to 12 miles from Cody, during the two years past, though the rails have been left down in case there shall be a sufficient tonnage of ore available for shipment from mines about Cody to make it worth while for the Great Northern to make the necessary renewals to bridges and trestles, damaged by snowslides, before traffic can be resumed. But even if the railway shall not again be operated, it will be practicable to provide for the transportation of Sunset ore by the construction of an aerial tramway down to the end of the wagon road the Provincial Government has had constructed up Cody Creek to within 2,000 feet of the Trade Dollar workings. This provision for facilitating the shipment of Sunset ore will most likely be made, if the ore shoots now being driven for shall prove up to expectations. Most of the work on the group has been done on the Cody side of the mountain, so that for this reason as well as considerations of cost, the tramway will be built on that side if at all.

The Sunset-Trade Dollar vein does not contain much concentrating ore; in fact the ore met with is practically all clean enough for shipment to the smeltery. What is not is of comparatively little value. An advantage here enjoyed is that when zinc is met with it is usually in bunches, not disseminated through the silver-lead ore, consequently the latter is clean. It is only in the slate country, though, that zinc occurs in the Sunset mine; the ore may be clean silver-lead and suddenly change to clean zinc. The present expectation is that in the future the Sunset mine will be found to contain much pay ore in the porphyry formation; if not, there is not much looked for in the slate. No. 7 tunnel crossed a porphyry dyke about 200 feet in width, and where the vein was in porphyry it produced freely ore of high grade. It is stated that the ore occurring in the porphyry runs higher in silver than that in the slate; it averages two ounces of silver or better per unit of lead in the former, while in the latter it runs only about one ounce and a half per unit.

One of the features of mining in the Slocan now rendering its future hopeful is that mine owners have recognized that in order to make the mines productive much well-considered development work must be done. In

earlier years the custom on most properties was to mine all the ore that could be reached without first having a lot of development work done, and to divide what profits there were, thus making no provision for ensuring the continued working of the mine after the shoot or shoots of ore should have been taken out. Recent years have witnessed a decided change in policy in this respect, and much development has been done, some of it at deep levels, and in several cases with most encouraging results. In degree the owners of the Sunset group have adopted this policy, and the outlook for their mine is that it will again be productive and leave a considerable margin of profit to reward them for their faith in its future and their enterprise.

The Bell Mine.

The following information concerning the Bell mine has been extracted from the "Report of the Commission Appointed to Investigate the Zinc Resources of British Columbia and the Conditions Affecting their Exploitation," published in 1906 by the Mines Branch of the Department of the Interior, Canada. The information was gathered by Mr. Philip Argall, M.E., of Denver, Colorado, U.S.A., one of the members of the Zinc Commission, who visited this mine, among others, in the autumn of 1905. Since that date the Bell has been inoperative, so there is little to add to Mr. Argall's report, in part as under:

"The Bell claim is situated at the head of Jackson Basin, on its eastern side, about three-quarters of a mile from the Jackson mine where the wagon road from Whitewater terminates. This road must be extended to the Bell before steady shipments can be made, except by pack or by rawhiding during the winter months.

"The upper, or No. 1 tunnel was started on a vein of zinc blende, one foot in width, continuing quite regular for ten feet from the portal, where an open fissure comes in, along which the blende widens out to ten feet and continues along the drift at a gradually decreasing width until a slip cuts it off, 30 feet from the portal, at which point the blende was only five feet wide. A stone in the roof from 10 to 25 feet from the portal shows a very good vein of zinc blende. A sample taken across the roof stope for a width of ten feet assayed, silver 2.2 ounces, lead nil, zinc 40 per cent. A small stope in the floor of the drift shows at a depth of five feet an almost solid vein of zinc blende eight feet in width, containing, however, some small ribs of slate, but showing in either end, nine feet apart, almost solid blende. This shoot or chimney of ore should go down for considerable depth and produce a fair tonnage.

"At a distance of 45 feet from the portal there is no vein to be seen, the slips that terminated the ore having reached the floor of the drift; but a cross-cut of 27 feet easterly reached what appears to be a parallel vein on which a drift extends 22 feet northerly, showing two small veinlets of zinc blende in very tight ground, and but a few feet in length. For 20 feet south of the cross-cut the drift is timbered, but from the end of the timbers to the face, a distance of 30 feet, a very solid lens of first-class zinc blende occurs that will average 30 inches in thickness. A sample taken from four cuts across this vein assayed, silver 2.1 ounces, lead 1 per cent., zinc 46.1 per cent. At the south face of the drift, 50 feet from the cross-cut, a porphyry dyke occurs which forms, or parallels, the hanging wall of the blende for some distance. About 30 feet south of the cross-cut a raise goes up ten feet, apparently reaching the top of the lens, which, however, continues strong and regular in the bottom of the level for the entire distance of 30 feet.

"Two other tunnels are opened below No. 1, but the formation and ore occurrence are different, and I am doubtful if either of these tunnels is on the main deposit opened in the upper tunnel. Two approximately parallel lenses are opened in the upper tunnel, as described, but in the absence of any connecting raises, or even a survey of the workings, one is not justified in pronouncing a positive opinion. Tunnel No. 2 passes through dark slate for 50 feet and then turns northerly on an irregular deposit, showing small veinlets of zinc blende and galena. A short stope or raise has been started at the end of this drift, showing in one place a small lens of galena 10 inches maximum thickness. A winze was also started under the raise, following down the galena, but was full of water. Judging from the ore on the dump some good grade galena and zinc blende had been taken out of these workings.

"The lower, or No. 3 tunnel, goes in for about 100 feet through graphitic slate, and then turns northerly. At this point a streak of zinc blende four inches thick can be traced diagonally across the drift for a length of 15 feet. A little further on a 5-inch parallel streak of fine-grained crushed and slicken-sided blende occurs for a length of 20 feet. At the end of the drift, which is 30 feet from the turn in the main tunnel, a raise or a small stope was found. The platform in the raise, covered with loose rock, prevented one from passing through it. The rock is black slate and the footwall smooth and well-defined, with a southerly dip of 60 degrees.

"The ore lenses are very irregular and have a peculiarity of running diagonally with the vein walls and terminating on contact with them. The 20 foot lens was sampled in three places, which averaged a thickness of five inches, and assayed, silver 2.2 ounces, lead nil, zinc 48.5 per cent.

"This property gives promise, when opened up, of being a good producer of zinc blende. It will be noticed that No. 1 tunnel shows rather a large vein of high-grade zinc blende, with practically no galena, while the lower tunnels show small irregular lenses of both galena and zinc blende, like the average Slocan veins. The deposit of high-grade, almost lead-free, blende in No. 1 however, more nearly resembles the Lucky Jim type of ore deposit."

The Lucky Jime Mine.

Mr. Argall also examined the Lucky Jim mine, which last year shipped more zinc than any other mine in British Columbia. Extracts from his published report follow:

"This property, situated at Bear Lake, Slocan, is owned by Mr. G. W. Hughes and associate. It consists of 12 mining claims and fractions, aggregating about 350 acres. The Lucky Jim vein was discovered in 1892 and worked irregularly for some years for silver-lead ore; during the years 1896-1899 concentrating ore amounting to 5,641 tons was produced, from which 1,600 tons of zinc blende averaging 50 per cent. zinc was sorted out. The remainder, a zinc-lead product, was sold to the owners of the Pilot Bay concentrating and smelting works. The 1,600 tons of zinc ore assaying about six ounces of silver per ton, three per cent. lead, and 50 per cent. zinc, was shipped partly to Antwerp, Belgium, and partly to the Fry process works on the Manchester Ship Canal, England, a special freight rate of $14.50 per ton having been secured from the mine to these works, but unfortunately the works, the process and its inventor all came to grief about the time the ore arriv-

ed in England and the shippers gained nothing but experience by the transaction.

"During 1901-2 the property was shut down, but it was re-opened in 1903 by Mr. G. W. Hughes, the present owner, who has declared dividends of $100,000 as the result of zinc ore shipments during 1904 and 1905.

"The production under Mr. Hughes' management up to the end of 1905 amounted to 5,345 tons of zinc blende averaging 54 per cent. zinc, a small portion of the tonnage being concentrates from a trial shipment to the Payne concentrator at Sandon.

"Development.—The property is developed by five tunnels, the uppermost worked exclusively for silver-lead ore and now abandoned, being situated at an elevation of 4,551 feet above sea level. The Slide tunnel, so called because its portal is situated on the slide of the gulch, in the track of a large snowslide, is at an elevation of 4,474 feet. A second tunnel (Safety tunnel) was driven in at this same elevation from a sheltered point on the side of the mountain and connected with the workings of the Slide tunnel, so that men can enter or leave the mine in safety when slides are running in the gulch.

"Two tunnels, one on the east and one on the west side of the gulch, have their portals at an elevation of 4,366 feet. These tunnels (called No. 2) are connected with the Kaslo & Slocan Railway by a gravity tram 1,300 feet long, with a fall of 830 feet. These tunnels, together with the branch levels, aggregate about 3,000 feet of drifts.

"Geological.—The Lucky Jim ore deposit differs so much from the general run of the Slocan vein series, that a short note on the geological conditions is necessary to a clear understanding of the ore occurrence at this very interesting mine. In a word, the ore is found in a zone of limestone and calcareous slate where penetrated by fissures, and invariably in the purer crystalline limestone of the zone. The footwall of the limestone zone is a hard dark green fissile slate, more or less pyritiferous near the plane of contact with the limestone. Impure quartzite beds occur in the footwall slates, but not in the vicinity of the ore deposits. The hanging-wall country, as seen in No. 2 tunnel, appears to be the average graphitic slate of the Slocan series. The foot and hanging country is separated by about 100 feet of calcareous slates, limestone, etc., that make up what I shall call the limestone zone. The pay ore occurs in chimney-like columns in the purer limestone, invariably along some line of fissuring, or extending along the fissure in vein-like form, where limestone forms one or both of the fissure walls. The fissuring, like most of the Slocan series, is greatest at the present surface, and becomes less in depth, the minor fissures often disappearing in less than 100 feet from the surface. These latter, however, are confined to the limestone zone, and are more properly called incipient fissures. The key to this ore deposit is, however, the east-west fissures crossing the strike of the limestone zone and this fact should not be lost sight of in prospecting at the Jucky Jim, or other properties along the strike of the limestone zone to the south."

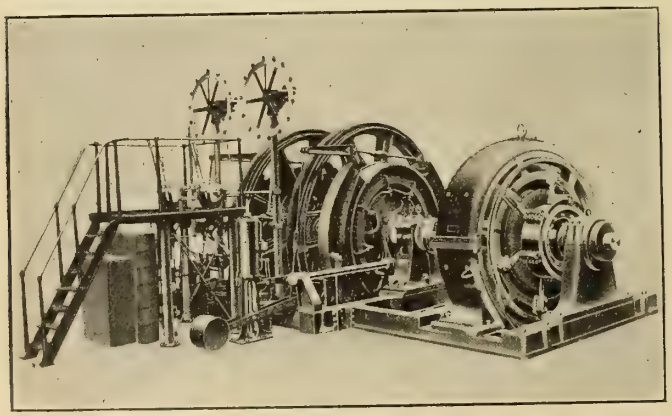
Mr. Argall's detailed description of the mine workings is too long for reproduction here. It may be found by those requiring to read it on pp. 201-6 of the Zinc Commission's report, above mentioned. Concluding, Mr. Argall observed: "The Lucky Jim ore deposits occur in a limestone zone in part interbedded with the slates. This zone consists of crystalline limestone of great purity, calcareous slates and dark impure limestone bands which in some places follow the strike of the slates and in other places are of irregular form, more particularly the crystalline limestone in which the two developed ore chimneys occur. The ore deposits occur in association with a system of vertical fissures crossing the zone at about right angles to its strike. The fissuring is best and largest near the surface and does not continue very strong in depth. Future prospecting should therefore take the form of developing the cross fissures at a shallow or moderate depth in the limestone zone. Moreover, the shallow deposits carry galena and very clean blende, while in the deepest workings a fine-grained pyrites and pyrrhotite occur in quantity, mixed with the blende, and hence the deep ores will require a concentration mill and magnetic separator to handle them effectively. The Lucky Jim mine should produce large quantities of concentrating ore as well as the high-grade zinc for which it is famous. Further development along the strike of the limestone will in the fissured zones undoubtedly result in the discovery of other deposits of high-grade blende."

Since the Zinc Commission made its report the Lucky Jim property has passed into other hands. In 1909 it was acquired by Mr. G. Weaver Loper, of Spokane, Washington, U.S.A., and associates, who organized the Lucky Jim Mines, Limited, and have been operating the property for more than a year. In February of that year the new owners obtained possession of the mine, and they were reported to have spent during that year about $50,000, including the cost of overhaul of machinery, erection of new buildings for the accommodation of the miners, and development work. The year's output of zinc ore exceeded 5,000 tons, averaging about 50 per cent. zinc. Besides cross-cutting, and sinking a winze from the upper workings, the driving of another tunnel was undertaken, at such a depth below the old workings as to give 300 feet more stoping ground on the dip of the ore. Production has thus far all been from ground above No. 4 tunnel. The new tunnel is 250 feet vertical depth below the lowest old tunnel in the mine. The present owners state that the ore occurs in fractures crossing the lime dyke, which varies in width up to 250 feet. The fractures are from 12 to 50 feet wide and in places are filled with zinc ore, and sometimes with lead and zinc ores mixed. The zinc ores run up to 54 per cent. zinc, and the lead ores 68 to 75 per cent. lead, with silver averaging about one ounce to the unit of lead. The quantity of milling ore available at the close of 1909 was estimated at about 60.000 tons, this containing 8 to 10 per cent. lead, 25 to 30 per cent. zinc, and 10 ounces silver per ton. This ore will not be utilized until after a concentrating mill shall have been erected and equipped. The proposal is to put in a plant that will supplement production up to a total of 1,500 tons of 50 per cent. zinc ore and concentrate. It could be noted that the estimated values of the ores as just given are higher than those quoted by Mr. Argall, but they are given as stated by a representative of the company.

Quite recent notes relative to this property are as follows: "An aerial tramway is being constructed from the portal of the lowest tunnel of the Lucky Jim mine down to the Kaslo & Slocan Railway below. Heretofore the zinc ore shipped has been sent down over a gravity tramway to the shipping bin alongside the railway. During the latter part of 1909 a tunnel was driven to cut one of the big ore shoots at greater depth. In December, at 380 feet in, this ore shoot was entered; now the tunnel is being extended towards a second big

shoot of ore distant between 800 and 900 feet from the mouth of the adit. This shoot should be reached by the end of June. About the same time the new tramway should be completed, for the cables are on the ground, timbers for the upper terminal and derricks are framed, and the ore bin at the lower terminal about finished. The length of this tramway will be approximately 1,000 feet. By the middle of July ore should be coming down from the lower tunnel, and thereafter shipments should amount to between 300 and 400 tons per week.

"The last winter's development work also included putting up two raises, each about 80 feet, from adit No. 4 to No. 3. One is through and the other within 10 feet of making connection. Between 30 and 35 men are employed, with Mr. Charles Norman as resident foreman. Mr. A. J. Becker, of Kaslo, is superintendent for the Lucky Jim Mines, Limited."



The Lucky Jim Company's head office is in Spokane, Washington, and Mr. G. Weaver Loper is managing director. He is at present energetically pushing the proposed concentrator erection scheme, and is determined to make the operations of the company both large and successful.

The Mountain Chief Group.

Not much information is available concerning this property, which is situated on the south side of Carpenter Creek, about a mile and a half from New Denver, this town being on Slocan Lake. There is an excellent wagon road to within a quarter of a mile of the principal tunnels, and thence to the mine there is a good pack trail. No work has been done on the property for several years, owing, it is said, to disagreement between two of the former owners. The ore lying on the dump, and some sacked at the mine, was assayed for the Zinc Commission, and showed that it contained fair value in silver, lead, and zinc. The value of the property as a prospective shipping mine is, however, under existing conditions, not ascertainable.

THE HECLA MINE HOIST.

The operation of large electric hoists, with mutual satisfaction to the mining company and the power company, has, during the past few years, received very careful consideration, and to-day there is no question but that this problem has been satisfactorily solved.

Hoist—Shop View.

With the introduction of the polyphase alternating current generators and high tension transmission lines, electric power has become available in most of the great mining districts. The simplest method of utilizing this power for hoist work is through the direct application of an alternating current induction motor. If the capacity of the hoist is comparatively small, this is quite satisfactory, but where heavy loads must be handled at high speed, the peak due to acceleration of the moving parts, is often far in excess of the average requirements of the hoist, in which case, if the current is purchased from a power company which also carries a lighting load, the voltage fluctuation at each recurrence of the hoist cycle peak will prove most objectionable. If the hoist is located at the end of a long transmission line, and excessive amount of copper must be installed to prevent an undue drop in the voltage during the maximum demand. In any case, the power company must install all its equipment with reference to the peak instead of the average load, and must

Hoist, as Installed.

charge accordingly. To meet these conditions the fly-wheel motor-generator type of hoist has been developed. The essential parts of such a hoist system are:

(A) A shunt wound direct current motor geared or coupled to the hoisting drums.

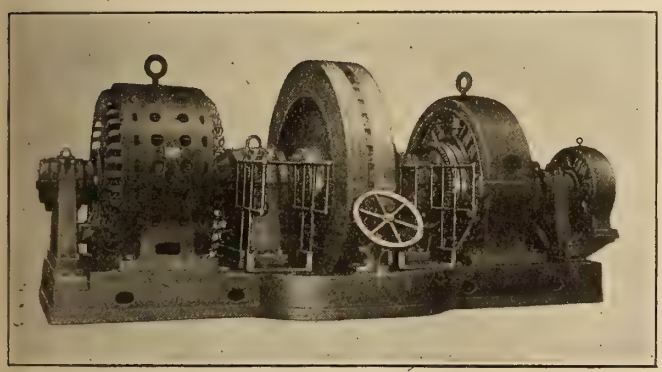
(B) A fly-wheel motor-generator set, consisting of

(a) An alternating current induction motor with variable external secondary resistance.

(b) A direct current shunt wound generator with auxiliary commutating poles.

(c) A heavy fly-wheel mounted on the motor-generator shaft.

(d) A direct current exciter for separately exciting both generator and hoist motor.



(C) A slip regulator which by varying the secondary resistance of the A. C. motor causes it to slow down under heavy loads.

(D) A suitable controller for varying and reversing the D. C. generator field current.

The armatures of the D. C. generator and hoist motor are connected in series and the field of each machine is separately excited, constant full field being maintained on the motor. The hoist is started by applying a gradually increasing field to the generator, thus causing a proportionate voltage to be impressed upon the armature of the hoist motor. When the load on the A. C. motor reaches a predetermined limit, resistance is automatically cut into its secondary circuit by means of the slip regulator. The speed of the motor-generator is thus reduced and a portion of the stored

energy in the fly-wheel utilized in overcoming the peak of the hoisting cycle, with a minimum demand on the power system. In stopping the hoist at the end of a cycle the generator field is gradually weakened so that any excess energy stored in the descending cage, rotating hoist motor, and drums, is returned to the fly-wheel through the D. C. generator, which momentarily acts as a motor, receiving electrical energy from the hoist motor, the functions of which are also momentarily reversed. To reverse the hoist, the field of the generator is reversed, causing the motor to rotate in the opposite direction. The heavy peak loads are thus eliminated from the line, and the wear on the mechanical brakes is very much reduced. Since the current handled by the controller is very small, a great many steps can be provided, giving the operator a very elastic and sensitive control under all conditions.

Perhaps no electric hoisting plant has attracted more attention from the mining men of the entire country than that of the Hecla Mining Company at Burke, Idaho; the American Institute of Mining Engineers during their 1909 tour, made the trip to this mine for the express purpose of inspecting the installation.

Motor, Generator Set.

The power available for this plant is 3 phase, 60 cycle current, ranging from 2,080 to 2,300 volts. The motor generator, Figure 1, is self-contained, having a cast iron base, four bearings, and shaft. A 450 h.p., 3 phase, 60 cycle motor drives the direct current generator, which is equipped with commutating poles to enable it to handle full load current at any voltage between 0 and 600 volts. The fly-wheel, weighing 30,000 lbs., is mounted on the shaft between the motor and generator, while the direct connected exciter is carried upon the shaft extension at the end of the set. The direct current 550-h.p., 600-volt hoist motor, operating at 60 r. p.m. (Figure 2), is direct connected to the main reel shaft by a flange coupling.

The control of the direct current circuit for operating the hoist is obtained by means of a lever, the forward movement of which starts the hoist in one direction, and the backward movement in the opposite direction. This lever is direct connected to a reversing field rheostat with a large number of points; since it is used to vary the generator voltage instead of cutting resistance into and out of the hoist motor armature circuit, economical operation is secured at all points, whenever conditions necessitate running at lower than normal speed. All the operating levers have the same direction of throw with a movement of less than thirty inches. They are conveniently grouped upon a raised platform, consisting of an iron frame and hardwood floor, with a suitable stairway leading from the engine room floor to the platform, and a brass hand rail enclosing the stairway and platform. The entire electrical equipment described above was supplied by the Westinghouse Electric & Manufacturing Company.

The hoist, Figure 3, which was built by the Wellman-Seaver-Morgan Company, consists of two reels, each capable of holding 2,500 feet of 3-8-in. x 4-in. flat rope. Under normal conditions the hoist operates balanced; that is, the empty cage descends as the loaded cage is raised. If desired, however, either reel may be operated independently of the other. The winding diameter of the reel varies from a minimum of five feet when empty, to a maximum of thirteen feet when the entire 2,500 feet of rope is wound up. Each of these reels is fitted with a Webster, Camp & Lane band friction clutch, post brake, and indicator.

The brakes, which are operated by means of combined air and oil cylinders and heavy counterweights, are so designed that they are set by the weights and released by means of air cylinders.

This hoist has a maximum hoisting speed of 2,400 feet per minute, and will handle an unbalanced load of 16,000 lbs. including rope, from a depth of 2,500 feet, yet its operation is the acme of simplicity.

The complete equipment, including the motor-generator set, hoist motor, slip regulator, switchboard and hoist, weighs over 300,000 pounds.

ONTARIO MINERAL OUTPUT FIRST QUARTER OF 1910.

Returns to the Bureau of Mines show that the output of the metalliferous mines and works of Ontario for the three months ending 31st March, 1910, was as follows:

	Quantity.	Value.
Silver, ounces	6,399,927	$3,041,158
Cobalt, tons	78*	14,485
Copper, tons	2,491	357,074
Nickel, tons	5,250	1,131,024
Iron ore, tons	6,735	15,034
Pig iron, tons	109,718	1,750,396

* Only cobalt paid for included.

Shipments from the silver mines of Cobalt and adjoining regions aggregate 7,155 tons, of which 6,094 tons were ore and 1,061 tons concentrates. The ore shipped averaged 864 ounces silver per ton, and the concentrates 1,066 ounces. Of the shipments, 271 tons of ore came from mines in the Gowganda region, containing 287,316 ounces of silver. For the corresponding quarter of 1909 shipments from Cobalt were 6,833 tons ore and 290 tons concentrates, containing together 5,628,860 ounces of silver, the increase for the quarter being about 14 per cent. During the three months there were treated at the silver reduction works of Ontario 2,053 tons of ore and concentrates, containing nearly 50 per cent. of the total yield of silver. Low grade ores continue to go to the United States, but the concentration of low grade material has become an established feature of the practice at Cobalt.

The nickel-copper mines of Sudbury were very active during the quarter, and turned out nearly double the quantity of nickel produced during the first three months of 1909, namely, 5,250 tons as compared with 2,794 tons. The output of copper was also larger, being 2,491 tons as against 1,906 tons during the first quarter of 1909. The movement of iron ore during the first quarter of the year is always small, as the season of navigation does not open until after the quarter closes. The output of pig iron was slightly greater than during the same period of 1909.

OUR EUROPEAN LETTER.

England at last steps into line on the question of providing proper mining rescue apparatus. Details of new proposals. Further colliery reports show big drop in profits but condition not unsatisfactory. Monks as early coal getters. Important opinions on electric power in collieries. A new oil mine locomotive. The Rand dividend season.

Exclusive correspondence of Canadian Mining Journal

London, June 18th, 1910.

The reproach is at last to be removed from England that she is one of the backward countries of the world in the provision of proper rescue apparatus for mines. Winston Churchill, for the Home Office, admitted in Parliament on June 16th, that the Whitehaven disaster had lent a stimulus to the discussion of this question. He announced that within the last two years coal owners in this country had spent $50,000 on experiments with life-saving appliances. While full recognition was paid to this enterprise, there was nevertheless a general agreement in Parliament that the work was one which should be undertaken by the Government rather than left to individual effort. Already in consultation with various experts, the Home Office has drawn up an important series of regulations which, if finally adopted, will have the effect of standardizing the work of rescue in coal mine accidents.

It is proposed that a central rescue station shall be established in each coal field, with sub-stations at each of the neighbouring mines. This central station will resemble a miniature coal mine, in which selected men from the mines of the district will be trained to use the oxygen breathing apparatus, and to make their way through all kinds of obstacles to reach the victims of a supposed disaster. At each central station there will be kept twenty complete sets of breathing apparatus, stocks of oxygen, and smoke helmets. A motor car also is to be kept in constant readiness to proceed wherever help may be needed.

At the sub-stations which will be established at each mine, there must be kept five complete sets of breathing apparatus, five electric hand lamps, one stretcher with oxygen appliance for bringing unconscious men safely through poisonous gases, one apparatus for reviving men overcome by choke-damp, and an ambulance outfit.

The central station is to be connected by telephone with all the mines in the district.

Annual reports of colliery companies that have come to hand since I dealt with the last group continue to show the effect of the drop in prices and of the coming into force of the Miners' Eight Hours Act in 1909. A decrease of about 11 per cent. in export values could not but fail to lower profits, and since it, unfortunately, happened that the cost of production increased through the readjustments rendered necessary by the new legislation, the industry has had to bear a double burden. Having regard to the cumulative influence of these factors, it is really a matter of congratulation that the various undertakings are able to make as excellent a showing as they do. The Welsh companies have undoubtedly been harder hit than any others, but the enormous extent of their trade has also enabled them better than most to stand the strain of the troublous times out of which they are now, one is emboldened to think, definitely emerging.

Taking thirteen concerns covering the whole country whose reports are just to hand, I find the average decline in profit is about 36 per cent., but the individual showing varies considerably. In one or two instances earnings have advanced and losses have been converted into surpluses; in only two cases has a previous profit become a deficit.

The big Welsh firms, such as Partridge Jones & Company, the United National, Locket's Merthyr and the Penrikyher Navigation, register reduction in profits ranging from 48 per cent. in the case of the United National to 60 per cent. in the case of Locket's Merthyr. There is, however, barely 12 per cent. between the maximum and the minimum, which demonstrates how evenly the South Wales field was affected in contrast to the much more fluctuating character of changes in other parts of the country. In each of the above instances the ordinary distributions were naturally lowered, but as the amounts paid were not below 7 1-2 per cent. and went up to 15 per cent., it cannot be said that an undue part of the past year's burdens were transferred to the shoulders of the ordinary proprietors.

Amongst the earliest coal getters in this country were monks. When President Simpson of the Institution of Mining Engineers had occasion to investigate some titles of mining royalties near Newcastle-upon-Tyne, he discovered that the monks of Tynemouth had carried on coal mining in Northumberland in early times, dating from the latter part of the twelfth century. These records had induced him to study also the history of coal mining in the neighbouring County of Durham, where he found that under the auspices of the monks of the Palatinate the industry had been carried on in various places with great vigour, which led him to conclude that they had been more extensive workers of coal than was generally supposed. Further investigations had elucidated the fact that in other parts of England as well as in Scotland and in Wales where coal existed in the neighbourhood of monasteries it had been worked by the monks. It was generally surmised that the Romans during their occupation of Britain worked coal, but there was not much evidence to that effect. There was, however, abundant evidence that they worked ironstone and other minerals. The accounts of working coal in Saxon times were scanty and obscure. Little working seemed indeed to have taken place until after the Norman Conquest. The President proceeded to give many details of the information which he had gleaned of coal mining by the monks, and the source of revenue which was thus afforded to the monasteries up till the time of the dissolution of these institutions.

The Mining Institute of Scotland has been discussing electric power in collieries. Two important papers were read, one by Frank Anslow and one by Robert Crawford and Harold Moores in collaboration. Frank Anslow discussed the controversy which is raging just now as to the relative advantages of three-phase and direct current for colliery work. He did not propose to enter into discussion at this stage other than to say that when a supply is taken from a supply company there is no option but to adopt the system at which the supply is given, if capital expenditure is to be avoided. For all practical purposes each system is equally dangerous, or perhaps it is better to say equally safe if properly installed under conditions suitable for the system selected. One of the main objections raised to direct current plant was upon the score of sparking. The improvements in the design of this plant had resulted in prac-

tically sparkless commutation even under severe overload conditions, but it would not be disputed that the danger of ignition of gas or coal dust from this cause still existed. However, this danger was also present with alternating current slip ring motors, and also in a modified degree with those of the squirrel cage or short circuited type.

On the subject of coal cutters, Mr. Anslow said that from a working point of view direct current coal cutters were superior to those operated by alternating current, but the latter type had proved itself quite reliable and satisfactory in working. In conclusion he remarked that given these essentials which had been present in all the successful developments of electric power in other directions, and which were even more necessary in colliery work, they could look forward with all confidence to the future of the power in the knowledge that it would not only outlive the suspicion with which it was at present looked upon, but would further extend its field of usefulness.

Crawford & Moores dealt with power production at collieries with special reference to gas power and electric centralization. They pointed out that the production of cheap power at collieries was a question of vital importance demanding more and more attention year by year in proportion to the drop in price of the saleable article, due to the pressure of highly competitive times, the comparatively less efficiency of colliery plants in general, and the increased depth at which the coal was being worked. The growing need for economy made the subject of power cost one to which the colliery manager must devote considerable attention with a view to transmitting and generating his power in such a manner as would ensure the highest possible efficiency. The report of the Royal Commission on Coal Supplies pointed out that collieries were extremely wasteful in the amount of fuel consumed in driving their own plant, the annual consumption in British mines reaching the enormous total of 18,000,000 tons. This was equivalent to about 7 per cent of the total output, while it was an ascertained fact that in some individual cases the consumption in the colliery boilers reached the high proportion of 11 per cent. This proved the urgent need for economy, and the intention of the present paper was to demonstrate that very high economies could be obtained by various methods and in varying degrees, according to individual circumstances.

The authors at considerable length illustrated how in their opinion savings could be effected in regard to non-bituminous pressure gas plants, non-bituminous suction gas plants, bituminous suction gas plants, and bituminous pressure gas plants, while they called special attention to the Mond gas plant, a type of plant which they considered to be adapted for power installations of over 2,000 horse-power. Finally, they argued that a gas-driven central electrical power station for a group of collieries was the ideal arrangement where circumstances admitted of the outlay which such a scheme involved; and there appeared to be no doubt that many such would spring into existence during the next few years with a view to using to the best advantage the heat possibilities of the coal consumed.

A most efficient and well-designed mine locomotive of the internal combustion type is being supplied by an English firm to German and Austrian owners. Owing to its special design and small wheel base, it can traverse the most confined mines' roads and turn curves of very small radius without losing engine power. A skilful arrangement also exists for the condensation of its exhaust gases. Powers run from 6 to 50 h.p., and they can haul loads varying from 15 to 150 tons at speeds from 4 to 14 miles per hour. The motor is an ordinary single cylinder one and ignition is effected by a low tension magneto. For underground haulage in fiery mines both terminals in accordance with Austrian regulations for coal mines are insulated and the current conveyed to and from the sparking points in special metallic woven tables. Further indication of the explosion proof character of the locomotive is given by the total elimination of any form of carburetter outside the cylinder. A 12 h.p. locomotive is found to consume during a ten hours' trip about 5 gallons of fuel and a saving of two-thirds in the cost can be shown as compared with horse haulage.

The Rand dividend announcement season has now well begun, and, roughly, about half the dividend payers have informed their shareholders what dividends are to accrue to them. The showing, as was expected, is not a very good one, and it becomes a matter of satisfaction to find so many companies maintaining the June distribution at the level paid in respect of the last half year of 1909. The only advances, so far, are the Consolidated Main Reef's 7 1-2 per cent. for the half year, and the new Goch 7 1-2 per cent. for the half year, as against its 10 per cent. for the preceding whole year. On the other hand, the Modderfontein goes back to the rate it paid in June last year, although something better than this had been expected in view of the provision of further working resources by the recent issue of shares at $55 each. This time there is no bonus with the Ferreira's return. Perhaps the best picture of the Rand returns is shown by working out the approximate yield per annum on a basis of the last twelve months' dividend and the current market price. Here, however, the exceptionally high yields are usually due to the remarkable period of the mines' life being comparatively short, and the exceptionally low returns sometimes discount better things in the future. Prominent in the former category figure the Ferreira and the Meyer Consolidated, Knight's Durban Roodepoort, Kleinfontein, Langlaagte, Simmer and Witwatersrand Deep, show up well amongst the mines with a fairly long period of life still in front of them.

NEW EMERGENCY SIGNALING APPARATUS FOR MINES.

The great value of an emergency signaling system for mine use, whereby a signal may be given simultaneously in every mine working, on every mine level, and reaching every man, is acknowledged by all mine operators. In some states the installation of such a system for the protection of the workmen in the mines has been compulsory by special legislation.

The value of such a system, which is used only in case of fire, flood or accident, is that its signal is an indication of danger and a command for every man in the mine to leave his work immediately and come to the surface. The size of the gongs for such a signaling system is required by law to be not less than eight

Fig. 1.

inches in diameter. The signal is thus made distinctive, differing greatly from the telephone and hoisting bell calls, and is so loud and clear as to reach for long distances in the mine levels.

The Western Electric Company has designed an emergency signaling system which meets the requirements of the laws of Illinois and other states for this service. It comprises a generator signaling set, as shown in Figs. 1, 2 and 3; emergency signal bells or gongs, as shown by Fig. 4, and the necessary wiring.

The generator signaling set consists of a strong metal case containing a hand generator and the line termi-

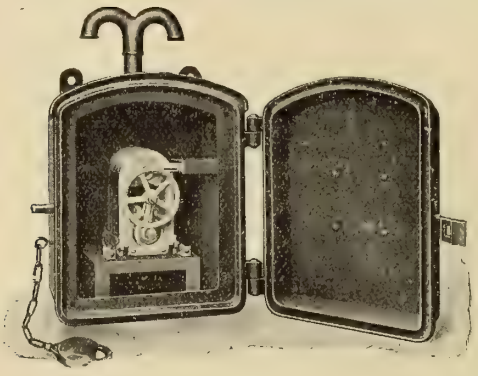

Fig. 2.

nals. It is provided with a strong hasp and staple and is locked with a padlock. On the front of the cover within a small box having a glass window, as shown by Fig. 1, hangs the key to the lock. Only in case of emergency the glass window is broken and the key used to open the set so that the crank which signals the alarm can be turned.

When the set is open for use a sheet metal partition protects the generator from injury, moisture, dust and foreign particles. Through this partition only the handle of the generator projects. The metal case of this set is protected by special treatment from rust and corrosion, due to gases.

The most important part of this signaling set, and, in fact, any emergency signaling system is the generator that supplies the source of the signaling current. In such a system the failure of the signaling apparatus involves serious consequences. Dry batteries are unreliable and inadequate as they deteriorate even when not in use, and need frequent inspection and renewals. A generator is the most satisfactory means of furnishing signaling current, as it is always ready to deliver current for an indefinite length of time and does not deteriorate either in use or when standing idle.

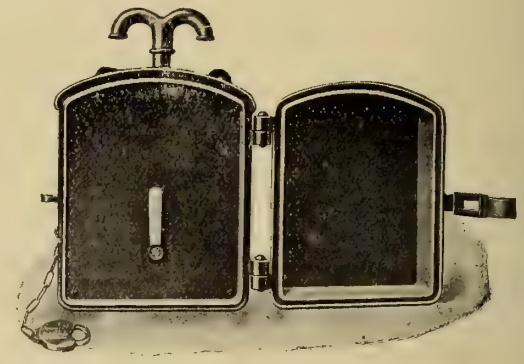

Fig. 3.

The hand generators used in the two new Western Electric signaling sets, come in five-bar and fourteen-bar sizes; each is a compact, durable and well-constructed generator, built for the most severe service. The magnets, both in the five-bar and fourteen-bar types, are of the highest grade tungsten steel and are hardened and aged to insure retaining their strength indefinitely. The bearings are large and well-proportioned. The five-bar generator is very efficient under practical working conditions and will ring perfectly the equivalent of twenty eight-inch loud ringing emergency signal gongs on an eight-mile full metallic line of No. 12 B. W. G. iron wire.

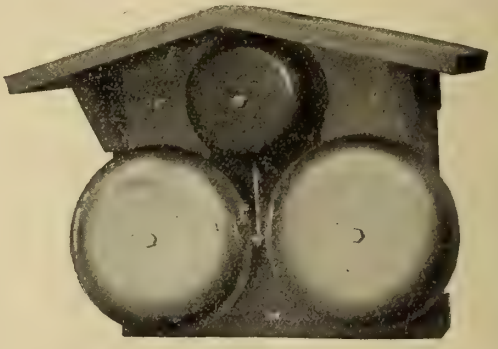

Fig. 4.

The larger generator equipment consists of a fourteen-magnet generator mounted in a metal case similar to that of the five-magnet equipment, but a little larger. This generator will ring the equivalent of sixty of the eight-inch gongs over an eight-mile line.

The generator of the signal set on this emergency system furnishes the current for ringing all the bells in the system. No batteries are needed and all the troubles of battery deterioration, failure and renewal are obviated. There are no switches to open and close —simply turning a handle rings all the bells. When

not in use the generator is on open circuit, and turning the crank automatically closes the circuit. The windings of each generator are specially treated with insulating material, making them moisture-proof and insuring continuous service.

The emergency signal bell, Fig. 4, of the Western Electric signal system, consists of a non-sparking bell provided with two eight-inch gongs mounted upon a backboard having a protecting canopy. The gongs are hot galvanized and have an especially loud, clear tone. All metal parts are specially treated to adapt them for use in mines.

The signal system above described may be used with or independent of a telephone system. For mine telephone service the Western Electric Company has new designs of metal and wood sets, and also a new design of an intercommunicating metal mine set, all of which are fully up to the standard of the telephone apparatus furnished to the telephone companies in the "Bell" system, who are its principal customers.

A UNIQUE TUNNELING MACHINE.

By Frank C. Perkins.

A most interesting form of tunneling machine has recently been devised at Denver, Colorado, the details of construction being shown in illustration Fig. 1, and drawing Figs. 2 and 3, while the method of operation of the same in tunnel work with electric locomotives for conveying the material as excavated from the tunnel is indicated in the accompanying illustration, Fig. 4. There is no doubt a great field for a practical machine for tunneling through hard substances, for, although the present process of drilling and blasting is effective, it is slow and costly. A blast is a dangerous thing, especially when used in close proximity to foundation.

It may be stated that the success or failure of any

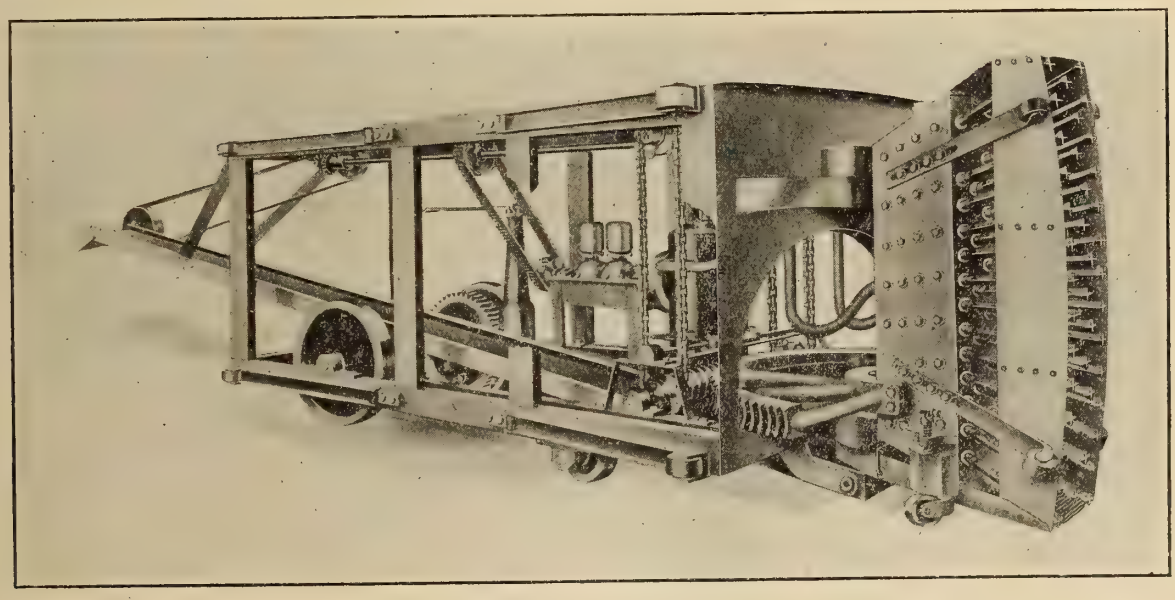

Fig. 1.

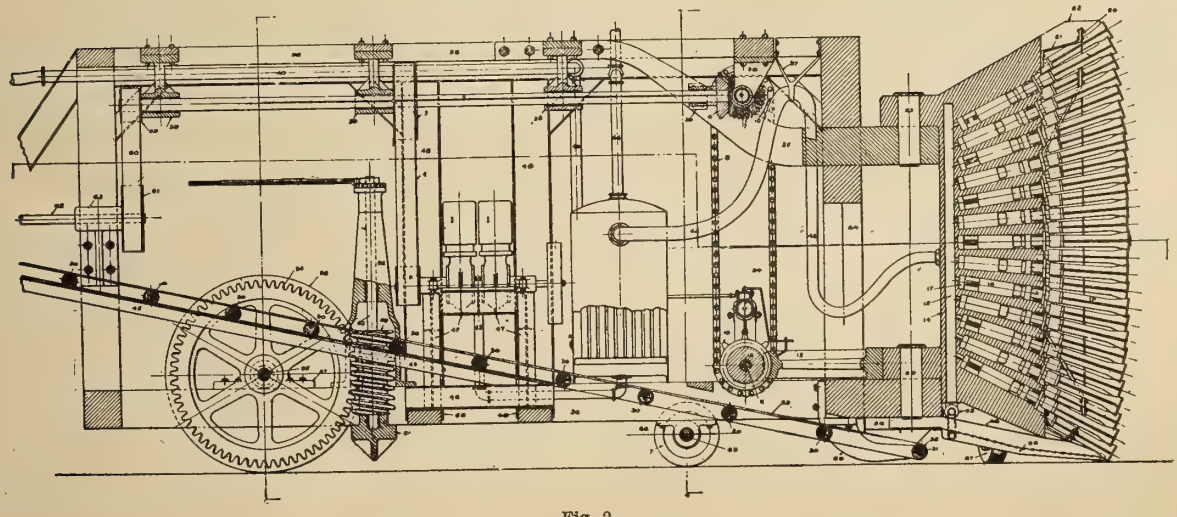

Fig. 2.

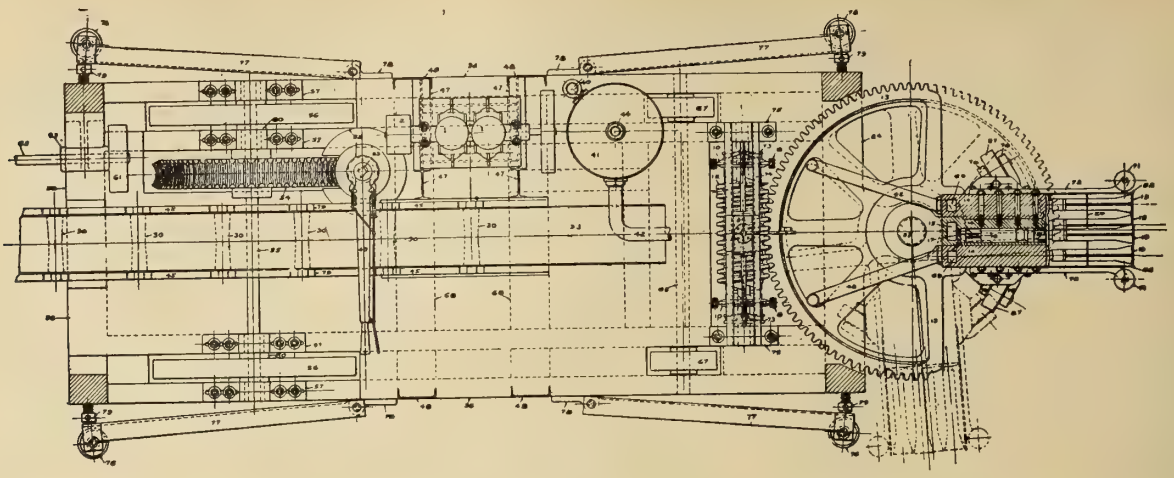

Fig. 3.

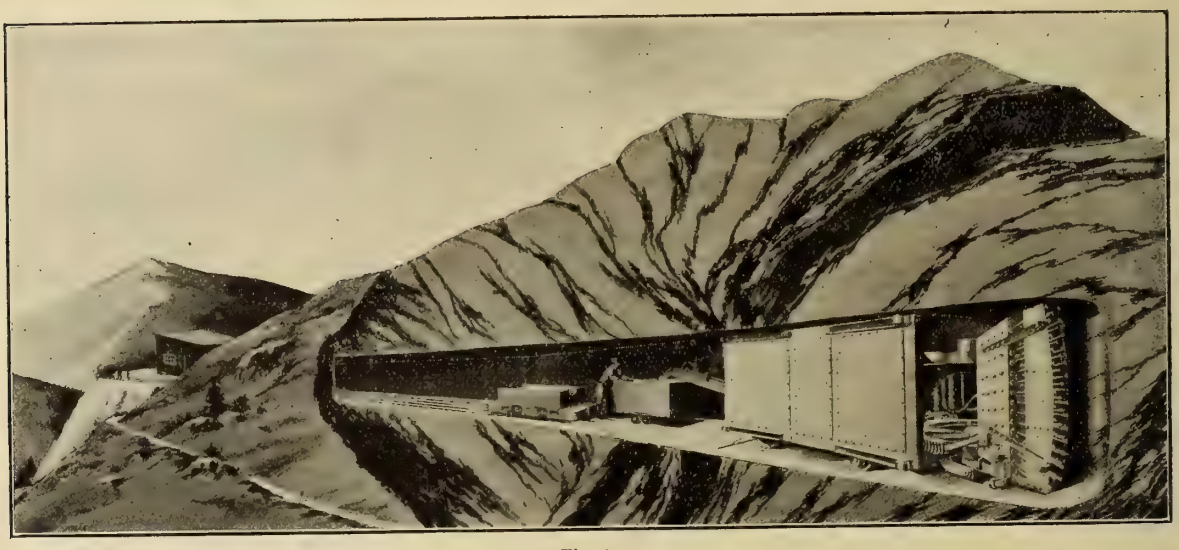

Fig. 4.

tunnel machine rests almost entirely in the effectiveness of its cutting head, which is the first consideration. The Fowler machine noted in the illustrations is equipped with forty-one hammer drills, which are used as a battery set into a casing of cast steel, hung by massive hinges to the frame of the machine. In operation, this battery of drills and the casting which incases it, is swung backward and forward, by means of a worm gear, across the breast of the tunnel.

It will be noted that the drills have no rotary motion but are arranged in the battery so as to slightly overlap in their work, as the cutting head swings from side to side.

It will be seen that the cutting battery is enclosed in a steel and rubber casing which snugly fits the roof, floor and face of the tunnel in such a manner as to inclose all cuttings, which are given just enough water to render them dustless. These cuttings are connected to cars at the rear of the machine by means of an endless conveyor.

As the cutting head occupies but a small portion of the breast of the tunnel, it is, therefore, possible to have free access to the surface of the breast at all times.

For power the drills are operated by compressed air and as each cutting unit strikes 600 blows per minute with a force of 1,150 pounds on each drill per blow, we have a force of 28,900,000 pounds per minute on the breast of the tunnel.

CANADIAN PATENTS.

The following is a list of Canadian patents granted on May 31, 1910, relating to mining and metallurgy, and furnished by Fetherstonhaugh & Co., 5 Elgin Street, Ottawa, Canada, Russel S. Smart, Resident, from whom all information regarding same may be obtained.

125961—T. L. Willson, and Maximilian Haff, Ottawa, Canada, metallurgical processes and products. T. L. Willson.

125969—A. P. Turner, Copper Cliff, Ont., converter hoods and flues. International Nickel Company.

125991—P. B. Martyn and Wm. Martyn, Audrie, Lanarkshire, Scotland, apparatus for the manufacture of metal grit.

125990—A. W. Catton and Chas. W. Cattons, West Seattle, Wash, regenerative furnaces.

126046—Jas. C. Kelker, Selby, Cal., apparatus for handling matte and the like products from blast furnaces, smelters and other reduction works.

Since the year 1897 no mercury ore has been mined in Canada. Pockets of cinnabar in quartz veins near Kamloops Lake, B.C., were the source of all recorded Canadian production. The maximum output, that of 1895, yielded 71 flasks of mercury, amounting in value to $2,343. The annual consumption in Canada is valued at about $100,000.

PLACER GOLD MINING IN BRITISH COLUMBIA.

Present indications are that this year there will be larger returns from placer gold mining in British Columbia than in 1909. This, by the way, is not saying a great deal for the industry, since the official records show that last year's production of placer gold in the province was the smallest in fifteen years, and less than one-half that of 1905, which in turn was smaller than that of any previous year since 1809.

There were exceptional reasons for the considerable falling off in production last year, but apart from these it is to be expected that the recovery of gold from old placer fields will show a gradual decrease under ordinary conditions, for the reason that the richer places soon become exhausted and as a result there is little inducement to individual miners to continue working where there is not much likelihood of returns being considerable to those working on the small scale on which as a rule individual miners must work. Generally speaking, the fields are thereafter either practically deserted or the gold-bearing gravel areas pass into the possession of companies or other large partnerships able to supply the capital requisite for the provision of plant and equipment for operating on a much larger scale than usually is practicable in the case of individuals. To the transition from individual to company ownership may in considerable measure be attributed the gradual yearly decrease in the quantity of placer gold recovered in British Columbia. Of course, there is also to be taken into account the great attraction new fields always have for the ordinary placer miner. Alaska has in recent years tempted many a miner from old placer fields on the Pacific coast to its far-off richer streams and beaches. The last, though, was not one of the reasons for last year's decreased production in British Columbia; rather was the decrease the result partly of the possession of the gold-bearing gravels by companies not then prepared to work them and partly the shortness of water and gravel-washing season for those who did operate their placer properties. It is believed, however, that the season now entered upon will see a change for the better, for not only are some of those whose operations last year were restricted by circumstances not then under their control now prepared for work on a larger scale, but there seems to be good reason to expect the water supply to be larger and the season's work proportionately longer.

In Cariboo.

The largest individual operator in Cariboo district in 1910 will be Mr. John Hopp, well known for years as a persistent believer in the eventual success of deep-drifting on Slough Creek, but who had finally to transfer his attention to the less costly hydraulic mining owing to the large amount of capital and lengthy period of work required to make the rich gravels of the old deep channel of Slough Creek accessible. During recent years Mr. Hopp has been gradually acquiring additional placer leases and water rights, chiefly in the vicinity of Barkerville, until now he has a property, or more correctly, several placer properties, which may be expected to be productive to an extent not reached for some time past in that district.

Last season was a very busy one on Mr. Hopp's properties and even after gravel-washing was at an end for the year work was continued, to get things in shape for extended operations this year. Bigger hydraulicking plants were placed on both Mosquito and Lowhee Creek properties. All the water as previously used for two small plants on Mosquito Creek is this year available for one larger system, and the ditches have been enlarged sufficiently to allow of their carrying the whole of the water any ordinary freshet will bring down. A No. 4 monitor was substituted for the two No. 1 size previously in use. The pressure on this plant is about 200 feet vertical head, with pipe 14 and 15 inches in diameter, and using 5 and 6-inch nozzles. It is planned to increase still further the supply of water by making another ditch, about four miles in length, which work will probably be undertaken this year. On Lowhee Creek the plant is larger than that on Mosquito Creek. Formerly a No. 2 Monitor was used on Lowhee, with pipe 11 and 15 inches in diameter; now a No. 6 Monitor does more effective work, having nozzles 6, 7 and 8 inches in diameter, and 16, 18, 22 and 30 inch pipe. For this property a new ditch, 5 1-2 miles in length, has been constructed, and the old ditch enlarged from 3 feet to 4 feet 6 inches in width for 2 1-2 miles. Capacity of ditch is now 2,750 miner's inches of water, under 400 feet vertical pressure to bottom of pit. In connection with the Lowhee plant a reservoir dam has been partly constructed; when completed it will be between 80 and 100 feet in height, but last winter it was built to a height of only 23 feet. It is estimated that the additional supply of water this reservoir will hold will increase the capacity of the plant for the season by at least one-third. About 2 1-2 miles of ditch have yet to be made to connect with the ditch completed last summer; also a flushing reservoir, the dam of which will be 15 feet high on Lowhee Creek a mile above the mine. When all shall have been completed as above outlined, the Lowhee, taking everything into consideration, will be, for its size, one of the best equipped hydraulic mines in British Columbia. Mr. Hopp is also working the Mucho Oro, on Stout's Gulch, and the Forest Rose, on the east branch of Williams Creek; operations on these properties are less important than those first above mentioned.

Other placer mining properties in Cariboo mining division are the following: Of the Lightning Creek Gold Gravels & Draining Company, on Lightning Creek; the Venture Mining Company, on Peters Creek; the Wormald Creek Mining Company, on a tributary of Lightning Creek; the Fountain Creek Mining Company, on Fountain Creek; the Thistle Gold Company, at Eight Mile Lake; the B. A. Lasell properties, on China Creek and Nugget Gulch; the Western Canadian Deep Leads, and a number of others on various creeks in the same division. There are also several deep-drift properties, on some of which much money has been spent in endeavouring to work the deep old channels of streams known to be gold-bearing.

In Quesnel mining division, Mr. John B. Hobson has an important hydraulic mine, which he will work this season, employing between 50 and 100 men. The biggest undertaking in this division, though, is that Mr. Howard W. DuBois is carrying out for Philadelphia capitalists, at an estimated total cost of about $1,500,000. The work in progress is the construction of a ditch and flume twenty miles from Swift River to the ground to be worked, which is at Twenty Mile Creek, on Quesnel River, about 20 miles below Quesnel Forks. The capacity of the ditch will be from 6,000 to 7,000 miner's inches of water. Included in the works are a dam of considerable size, and an inverted syphon 6,000 feet in length and 60 inches in diameter, with a pressure of 90 feet at its deepest part.

Incidentally it may be noted that latterly more than half the placer gold recovered in the province has been obtained from mines in the Cariboo district.

In Cassiar.

Cassiar district during several years prior to 1908 produced more gold than did Cariboo, but for two years it has taken second place in this respect. Its chief gold field is Atlin, the other divisions — Liard, Stikine, Skeena, and Queen Charlotte—together contributing but a very small proportion of the total gold obtained yearly in the district. Atlin gold field was discovered in 1898. Official records show an aggregate value of about $4,700,000 as that of the gold recovered on its streams during twelve years to the end of 1909, but unofficial estimates give a higher total—in excess of $6,000,000. The highest yearly total on record was that of 1899, of $800,000, while 1904 came next with $530,000. Since the latter year there has been a steady decrease in production recorded, until that for last year reached the lowest on record since the year of discovery—only about one-third of the value of the production in 1904. However, it is thought the turning point has been reached and that the yield will be larger in this and following seasons than in quite recent years. The number of individual miners working on Atlin creeks has become quite small in comparison with that in the earlier years of the history of the camp. There are also fewer companies operating there than several years ago. The larger hydraulic operators are the North Columbia Gold Mining Co., Pine Creek; Amalgamated McKee Creek Mining Co., McKee Creek, and Societie Miniere de la Colombie Britannique, Boulder Creek. Much information relative to mining at Atlin is contained in a paper, by Mrs. Rosalind Watson Young, M.A., of Victoria, B.C., printed in the "Quarterly Bulletin of the Canadian Mining Institute," No. 7, July 1909. Mrs. Young wrote from personal observation and knowledge of placer mining operations and conditions in Atlin camp.

There is little of importance to mention concerning placer mining in other parts of Cassiar district. Two hydraulic enterprises in the Dease Lake Country, Liard division, from which good returns had been expected, have suspended operations, lacking money to continue necessary preliminary work. The Ingenika diggings, of which much was heard two years ago, seem to have proved of small value. Quite recently, however, reports have reached Victoria of gold in payable quantity having been found on a tributary of Taku River, but little is yet known beyond the fact that coarse gold has been discovered. The new find appears to be in country situated between Telegraph Creek and Atlin.

In Other Parts.

Placer mining is being continued on a small scale on White Horse and Perry Creeks, upper Moyie River, and other streams in East Kootenay. In the Big Bend of the Columbia district, north of Revelstoke, which is in the northern part of West Kootenay district, there will probably be more hydraulicking done this year than last. Not much is looked for from streams in the Similkameen, Yale, or Ashcroft divisions, but there may be better results in Lillooet district than during the last few years. Operations in the western part of the Boundary district will not add much to the year's production, nor is it expected that Vancouver Island will yield any quantity of placer gold worth noting.

Reviewing the situation as a whole it seems that first from Cariboo and next from Cassiar may larger returns be expected this year, but not from other parts to any considerable extent.

A MINISTERIAL VISIT TO SULPHIDE, MADOC AND DELORO.

For long it has been the desire of the Hon. Mr. Cochrane, Minister of Mines for Ontario, to inspect personally the mining industries of Eastern Ontario. Pressure of routine business (and the Minister of Mines is kept quite as busy as the hardest working deputy) has heretofore prevented this. But on the morning of Thursday, June 23rd, the decisive step was taken, the ships were burned, and the Minister, accompanied by Dr. W. G. Miller, Mr. E. T. Corkill, and Mr. J. C. Murray, editor of the CANADIAN MINING JOURNAL, boarded the train.

Taking the east-bound C. P. R. express at 9 a.m., the party reached Tweed shortly after noon. Here a motor car was in waiting. The spin to Sulphide was delightful. A detour was made round one of the lakes and Sulphide hove in view, surrounded by groves of shade trees. Manager Deblois showed the party over the works and the mining plant. A short inspection of Mr. B. A. C. Craig's pyrite mine, situate less than half a mile from Sulphide, concluded round one. A very pleasant breathing space was afforded when Mrs. Deblois, the manager's wife, entreated the party most hospitably at their charming residence at Tweed. The motor then took the road for Madoc.

The fourteen miles between Tweed and Madoc were all too short. All Canadian scenery is beautiful in summer; but the County of Hastings has a charm all its own. The country is dotted with farms, groves of hardwood, lakes, and quaint streams. Its topography is sufficiently varied to remind one sometimes of an ideal English landscape, and sometimes of the highlands of Nova Scotia. The roads are good, grades are not excessive, and there are long stretches where one's craving for speed can be amply gratified.

Several mild adventures befell the motorists. A company of young pigs performed astounding gymnastic feats in their attempt to climb a four-foot fence. Similarly a covey of hens acted in a manner truly feminine. But for sheer stupidity honours seemed to be equally divided between the casual cow and the male human being. Only few horses, mostly of the vintage of 1880, displayed a violent interest in the progress of the car. Their masters made much more fuss.

On the road from Tweed the first glimpse of Madoc is caught just as one passes the easterly corner of Moira Lake—a lake, by the way, that deserves its name. It is as lovely a sheet of water as the heart can desire. Some Christian re-christened it Moira. Formerly it was known as Hog Lake.

The party was safely bestowed at the St. Lawrence Hotel, an hotel with a reputation, shortly after 6 o'clock. News was received here that a formal dinner was impending. This turned out to be true, for at 9.30 p.m. the dining room of St. Lawrence Hotel was thrown open and sixty or seventy citizens sat down to a meal that will be long remembered.

The Madoc Board of Trade were the hosts, and the Hon. Mr. Cochrane and his party the guests of honour. Mr. W. A. Hungerford occupied the chair, and occupied it well. To say that the menu was varied is putting it mildly. But it was more than varied. Every dish was completely edible.

Amongst the principal speakers were: Mr. Hungerford, the Hon. Mr. Cochrane, Mr. Thomas Cross, Mr. Pearce, M.P.P., Mr. Dale, Dr. W. G. Miller, Mr. E. T. Corkill, Judge Fraleck, and Mr. J. C. Murray.

Judge Fraleck and others drew the Minister's attention to the disability under which the district laboured

on account of the fact that the Canada Company, an ancient and parasitic English growth, holds the mineral rights over enormous tracts. Mr. Dale, who is a prominent local banker, advocated the guaranteeing by the Government of bonds to facilitate the establishment of a local customs grinding plant for grinding all suitable classes of minerals. Dr. Miller referred felicitously to the plucky pioneer work done by the chairman, Mr. Hungerford, by Mr. D. K. Stewart, Mr. S. Wellington, Mr. William Cross, Mr. Arthur Coe, and other citizens. Mr. Corkill dwelt upon the business aspects of measures for preventing accidents. Mr. Thomas Cross, in a speach sparkling with true humour, harked back to the past and kept his audience spellbound. As Mr. Cross is an indefatigable prospector himself, his words of cheer were heartily received. Mr. J. C. Murray emphasized the point made by Judge Fraleck concerning the Canada Company. He also corrected a misapprehension on the part of one speaker, who had referred to the "unearned increment" that may accrue to miners. Mr. Murray asserted that the term was an absolute misnomer. The miner deserves all he gets.

The dinner wound up with a warm vote of thanks to Mr. John Cochram, the proprietor of the St. Lawrence, for the pains he had taken in preparing such an entertainment in so short a space of time. Hardly ten hours' notice had been given.

Friday morning was occupied in looking over the Henderson talc mine and G. H. Gillespie & Company's mill. A quick run was then made to Deloro, where Mr. P. Kirkegaard and Mr. S. Wright conducted the party through the extensive plant of the Deloro Mining & Reduction Company. After a delightful luncheon at Mr. Kirkegaard's residence, the road to Marmora was taken. At this mining town Mr. Pearce, M.P.P., showed the visitors the chief points of interest. At 3.30 p.m. the west-bound express was caught at Central Ontario Junction and the visitors returned to Toronto pleasantly wearied after two strenuous days of sight-seeing and hospitality.

. . . . . .

Few Toronto people realize that within a short railroad journey there lies a mining country so fraught with historic interest and with present opportunity. Moreover, the motorist will find nowhere a more charming land wherein to risk his own and others' necks.

BOOK REVIEWS.

TELEPHONOLOGY--A DESCRIPTION OF MODERN TELEPHONE APPLIANCES, ETC., BY H. R. VAN DEVENTER, B.S., E.E. SPECIAL ARTICLES BY EMINENT EXPERTS. 586 PAGES, PROFUSELY ILLUSTRATED, PRICE $4. McGRAW-HILL BOOK COMPANY, 239 WEST 39TH STREET, NEW YORK.

The complicated science of telephony is the subject of this substantial volume. Every important phase of modern telephony is explained. Wireless telephony is not omitted. Although a large amount of detail as to construction and installation is presented, general principles are given a full share of attention.

The modern mine manager cannot afford to be ignorant of telephony. When he digests "Telephonology" he will have mastered the science.

THE CORROSION AND PRESERVATION OF IRON AND STEEL, BY ALLERTON S. CUSHMAN AND HENRY A. GARDNER. 373 PAGES—NUMEROUS HALF-TONES AND DIAGRAMS—PRICE $4. McGRAW-HILL BOOK COMPANY, 239 WEST 39TH STREET, NEW YORK, 1910.

Preservation is one of the first laws of engineering, and one of the fundaments of conservation. Conservation, in its narrow colloquial sense, is made to apply only to natural resources. But its meaning is fuller than that. Everywhere the observer can see unmistakable evidence pointing to waste and loss of finished materials. Nothing illustrates this better than the widespread custom of permitting iron and steel utensils, implements, structural parts, etc., etc., to remain without protection against the weather. On the other hand, the rapid depletion of our richest iron ore deposits accentuates the present need of directing our energies towards the efficient prevention of waste through corrosion.

The volume before us embodies the latest and most definitive knowledge of the phenomena of corrosion, and presents the best known methods of prevention and preservation. No effort, apparently, has been spared to mention or include all recent matter touching on the subject.

The extraordinary growth of what we may term industrial science and the evolution of practical chemical knowledge as applied to the manufacturing industries are nowhere better exemplified than in the book before us. It is now possible indefinitely to lengthen the life of steel and iron. Hence one step has been taken towards conserving our raw materials, our ores and metallurgical fuels.

The chapter-headings of "Corrosion and Prevention" will give the reader a bird's eye view of its scope.

CHAPTERS—

I.—The Problem of Corrosion.
II.—Theory of Solution.
III.—Theory of Corrosion.
IV.—Application of Electrolytic Theory.
V.—The Inhibition and Stimulation of Corrosion.
VI.—The Technical Protection of Iron and Steel.
VII.—Relation of Pigments to the Corrosion of Iron.
VIII.—Recent Field Tests on Protective Coatings.
IX.—Paints for Various Purposes.
X.—Testing and Design of Protective Paints.
XI.—Properties of Pigments.
XII.—Properties of Paint Vehicles.
Appendices, etc.
Bibliography.

Whilst the last word in scientific investigation is included, the book is also thoroughly practical. It will be found most helpful by all interested in the use of steel and iron.

One most commendable feature of the volume is an admirably arranged bibliography covering 63 pages.

PORTLAND CANAL ANALYSES.

Assays of some typical Portland Canal (B.C.) ores have been reported thus:

	1	2	3	4
Gold	0.20 oz.	0.20 oz.	0.24 oz.	1.20 oz.
Silver	20.00 oz.	18.0 oz.	26.66 oz.	48.80 oz.
Lead	7.96 p.c.	9.28 p.c.	11.61 p.c.	4.29 p.c.

All but No. 4 are run-of-mine ores. No. 4 is the assay of a rich streak.

The most abundant minerals are pyrite, pyrrhotite, galena, blende, and chalcopyrite, with which are associated gold and silver. Native silver is frequently encountered in considerable quantities. Gold, while it occurs persistently, appears to be irregularly disseminated. Apparently, also, gold fluctuates with the silver.

Correspondence.

QUEBEC PLACERS.

To the Editor of CANADIAN MINING JOURNAL:

Sir,—All legitimate prospecting, and the circulation of real mining news is to be commended, but such stuff as has been going the rounds of the press lately so evidently emanates from that class of prospectors whose experience is acquired in brokers' offices and around the fountain in Victoria Square that its purpose is easily seen, and it is sprung on the non-discriminating press with a view to the short-lived glory of the lime-light, or for the purpose of "seeing some capitalists."

The result, to mining men, of the appearance of such absurd items is to discredit all mining news that appears in the same papers. The art of discrimination in mining, as in other news, should be learned in the editorial sanctum sanctorum.

The class of prospector-promoters alluded to above is doing much to make this province appear ridiculous in the eyes of the mining world. Recently some New Englanders were enthused to the point of sending a man hundreds of miles to examine and report on one of these mares' nests which they had optioned for a high figure. He reported it absolutely without mineral values, and backed his opinion with assays—result, a cold wave in New England and a black frost in Montreal. The report, true to facts, pleased neither party. In this case the holders of the claims appeared to be sincere, but had been misled themselves by others.

Again, some of these metropolitan prospector-promoters with a pull got a few acres about 999 miles from Sherbrooke, and after the usual ebullition of super-heated caloric, hied them thither with a couple of young men in tow who had money to burn. A pan, taken from surface gravel, yielded a nugget as big as a soldier bean. The man who brought it from town for the purpose was the first to cast his cap in the air and yell with surprise. But capital was cautious, and demanded more nuggets—it was such easy money. Unfortunately, the jeweller from whom that one was bought had had only the one, and, as capital clung to that one, the prestidigitator couldn't produce.

And now the story of a remarkable find of what has long been known to exist along the Arnold and other small rivers in Woburn and all south-eastern Quebec has been going the rounds of the press in a way no mining news item was ever known to without propulsion from the rear.

The gold on these streams has never been found in quantities to pay for working by any method hitherto tried (though in some places solitary miners have made, perhaps, fair wages for a few days) except in Ditton, whence some thousands were taken by the crudest methods years ago, and by gouging out the cream of the ground. But the gravel on almost any stream in the valley of the St. Francis will yield colours. Imagine, then, 25, 50 or more pans worked down to the black sand and perhaps a few cents' worth of gold, in all say a half or a whole tea-cup full, sent for assay. Of course the returns will be thousands of dollars to the ton—of black sand—but they won't state how much gravel must be washed to get a ton of black sand. (This sand often contains minute jewels, such as garnets, but is of no appreciable value in itself or for the jewels). Such an absurd test as this made on ground that won't run 50 cents per cubic yard will show values in thousands per ton of black sand. No mining man would write, take stock in or print such stuff, as is very evident when, in reference to placer ground, we read such phrases as "the richness of the ore," etc.

Rich or fair placer or other finds will be welcomed by all who have the mining interests of the Province at heart, but we want the truth, rightly told, not absurd and evanescent sensationalism that can do no possible good even to the originators.

Yours truly,
G. R. E. KENNEDY.

"THAT TIMMINS SAMPLE CAR."

To the Editor, CANADIAN MINING JOURNAL:

Sir,—While quite approving of your word of caution in regard to the Porcupine district, I think I can go you one better in the way of *hopes* and *beliefs*. After my visit to the district I have sufficient ground for *belief*, though I have not sufficient for definite *knowledge*.

I *believe* that Porcupine is going to give us a very important output of gold. I *believe* there are going to be paying mines in the district. I also believe that there are going to be many wild-cats and many disappointments, as there are in every healthy mining camp.

In regard to that sample car I have no special information on the subject, but I think I understand it. In the first place I have not heard anywhere that the owners of the carload have based any broad claims in regard to it. They have given the matter no publicity except to their intimates. They are not selling any stock to the public.

The car load was not supposed to be representative of the camp, nor even of any particular vein; but I believe the samples were taken without any sorting or picking, and were representative of those parts of the vein where the samples were taken, and not just of rich spots and seams. I have seen both the surface and the underground quartz from the veins on the Timmins Syndicate claims, and if they chose to sort or pick their ore they would have no difficulty whatever in shipping a car load that would assay many times as high as this shipment. A car load of three samples will not prove a camp, nor even a claim, but this shipment must have been a source of considerable satisfaction to the owners. My only regret is that it should go all the way to New York to be sampled, but that is a matter entirely at the pleasure and discretion of the owners. I am not in accord with this outfit in the matter of this very expensive sampling, nor in the idea of sampling a claim with a stamp mill—Tremain or otherwise—but the highest credit is due to them for the way they have tackled this new district. Two years ago I came away from the Laker Lake district thoroughly disgusted with the way operations were being conducted up there, as I explained at the time in this journal. My recent visit to the Timmins Syndicate camp gave me the keenest pleasure and satisfaction.

Yours faithfully,
H. E. T. HAULTAIN.

J. C. Murray, Esq.,
Editor, CANADIAN MINING JOURNAL,
Toronto, Ont.:

Sir,—I have before me the Toronto "Star" of June 11th, with an article on air supplied this camp by the Cobalt Hydraulic Power Co., in which they say, "it also causes the men to bleed at the nose, and suffer

from buzzing in the ears, headaches, and other symptoms of partial suffocation."

As we are not interested either directly or indirectly with this company, I think it only right that this should be denied. I have not heard of a single case in this camp of miners being affected in any way, except those on contract work, and it certainly has increased their footage considerably.

I have written the editor of the Toronto "Star" regarding this, and hope he will correct same.

Yours truly,

THE CONIAGAS MINES, LIMITED,
per R. H. Royce, Asst. to President.

PERSONAL AND GENERAL.

The Nelson Iron Works of Nelson, B.C., has taken over the business and stock of the Rossland Engineering Works, of Rossland, B.C., and will succeed that company as British Columbia agents for the Sullivan Machinery Co., of Chicago. An increased stock of Sullivan rock drills, diamond drills, hammer drills, air compressors and supplies for these machines will be maintained at Nelson.

The latest circular issued by the Link-Belt Company, Booklet No. 95 (revised), covers a wide range of the products of that enterprising company. Tipples, retarding conveyors, car hauls, and coal washers are described and illustrated. The half-tones are taken from photographs of actual working installations. The pamphlet will prove useful to all workers in coal.

Mr. James Hargreaves, M. E., has opened an office at Room 34, 124 McDougall Avenue, Edmonton, Alberta. For more than twenty years Mr. Hargreaves has been identified with Canadian coal mining. His wide experience in the west was preceded by a long and thorough training in the coal mines of Nova Scotia.

Prof. J. C. Gwillim has been elected a Member, and Mr. Alex. Longwell an Associate, of the Institution of Mining and Metallurgy.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay.—Following the return of the U.M.W.A. strikers to work, matters seem to be going smoothly enough. There has been dissatisfaction amongst those strikers who have not been able to obtain work, but this cause of complaint is being rapidly removed. Some 300 men were left over when all the vacant places had been filled, and to give work to these men the Coal Company are arranging to double-shift No. 6 Colliery. No. 3 Colliery is already on double-shift, and when No. 6 follows suit, the company will have the largest number of workmen at the collieries in the history of the mines. The number of strikers who returned to work tallied with the figures which from time to time were given out by the company. During the strike it was stated on several occasions by responsible officials of the United Mine Workers that the number of men who went on strike at the mines of the Dominion Coal Company was over 5,000. It may be of interest to state that even to-day, when the force of workmen at the collieries includes the P. W. A. members who remained at work, the bulk of the men imported during the strike, and the returned strikers, the total number of men at the collieries, surface and underground inclusive, does not exceed five thousand men. There must have been something wrong with the U. M. W. A. calculation. The United Mine Workers' Journal in its last issue states that 400 miners are on strike at Inverness. Actually there is no strike at Inverness, and the mine is fully manned.

A significant accompaniment of the U. M. W. A. agitation is the rise of the Socialist party in Nova Scotia. The Cumberlan Labour party has been formally declared defunct, and those who were prominent in its leadership at one time are now avowed exponents of the social revolution. The Socialist Party is increasing in numbers in Glace Bay, and they intend to nominate a candidate for the next parliamentary elections. One of the most active of the local Socialists, in expressing his views in the U. M. W. Journal, uses as an argument in favour of socialism that "it is for the workingman, and **him alone.**" No doubt it is just as well to be candid about it.

Dominion Coal Output.—The annual production of the Dominion Coal Company during the years 1906, 1907, and 1908 remained almost constant in the neighbourhood of 3,550,000 tons. But for the depression in the coal trade the production for 1908 would have been 3,750,000 tons, but although the mines of the company have a productive capacity of at least this tonnage, owing to trade depression and labour troubles, the three and a half million has up to the present not been exceeded. Present indications point to an output for 1910 of between 3,400,000 and 3,500,000 tons. The production which will be necessary to reach these figures will be 300,000 tons in excess of the production during the second half of 1908, or in other words, the probable output of the Coal Company for the second half of this year will be at the rate of 4,000,000 tons per annum. The company has now in operation thirteen collieries, and two collieries in the construction and development stage. Out of the thirteen collieries in full operation, no less than seven are new and expanding mines. At one or two of the older mines, such as Reserve, Caledonia, and International, the outputs will gradually decrease, but this decrease will not become very marked for several years to come. In the meantime the new mines will have become large producers. It may therefore be expected, if labour troubles are averted, that the Coal Company's coal production during the next three years will reach very high figures indeed, when compared with past records. It would not be surprising during the present summer, indeed, to see daily outputs in the vicinity of 16,000 tons. To reach this figure, however, would require almost ideal conditions, and at colliery work, as one manager expressed it, "there's always something, or else going to be."

Colliery Explosions and Barometric Pressures.—In your correspondent's last letter reference was made to a statement, evidently inspired, that a "colliery warning" had been issued immediately before the Whitehaven Colliery explosion and fire, and the inference which some newspapers took that had attention been paid to this "warning" the disaster might have been averted. The imputation of carelessness has been hotly denied by most of the colliery journals in England, and the incident has occasioned much newspaper correspondence. It has been clearly demonstrated that the influence of changes in the atmospheric pressure varies with the local characteristics of a coal mine. In places where the surface cover is light and the strata is broken, it is evident that atmospheric pressure will act in a different manner than in a mine such as the one at Whitehaven, where the workings are five miles under the sea, where any changes in atmospheric pressure are modified or neutralized by the ventilating pressure. One of the writers quotes from the Report of the Royal Commission on Mines (1909), the following: "They (the "Colliery warnings") are misleading, and so far as we can see, their publication serves no useful purpose. We do not wish to underrate in any way

the value attaching to an intelligent appreciation by colliery managers of barometric changes, but we think that more harm than good is done by the issue of irresponsible notices of this kind.'' This, from such a source, is strong language, and should effectually dispose of any further newspaper criticism. The same writer remarks: ''Those officials are also more capable of forming an opinion as to what conditions affect the safety of the pits under their charge than an anonymous association which is shown, by the character of its utterances, to be innocent of that branch of scientific mining on which it professes authoritative knowledge.''

The Whitehaven disaster has given an impetus to the agitation for the provision of breathing appliances for rescue and fire-fighting work at collieries. The Home Secretary shortly after the disaster asked the colliery company to provide such appliances, and to arrange for their men to be instructed in the use of the same. Commenting on this the ''Colliery Guardian'' remarks: ''We have already expressed our opinion that, in order to be of use, the apparatus must be kept on the spot.''

ONTARIO.

Cobalt.—A few years ago New Ontario was practically unknown to the outside world, and not until the discovery of the riches of Cobalt was much attention paid to it. Even then for several years the energies of the prospector were centred upon the search for silver, and this resulted in the discovery of South Lorrain, Gowganda, and other camps. As the possibilities of these fields became better defined, the prospectors were forced out into the hitherto unexplored parts, and then followed the discovery of the Porcupine gold district. The latest new development is the rediscovery of iron near the Grand Rapids on the Mattagami River. These deposits were first noticed by the Geological Survey over thirty years ago, and six years ago it was again reported on by the same department. It was stated to be a very important deposit of limonite, containing a high percentage of iron, and free from sulphur and phosphorus. A syndicate has recently become interested, and has staked a number of claims. These are within a few miles of some of the lignite claims which gives them additional importance. The present railroad expansion in this part of the country, coupled with the fact that the Hudson Bay line may be started before long, is responsible to a great extent for the increased interest in mining possibilities in New Ontario. The search for precious metals has retarded development in other directions, but the unexplored area is large, and chances for the future are brighter than ever before.

The McKinley-Darragh will in future pay quarterly dividends instead of half-yearly as formerly. The next dividend, which will be payable July 15th, is at the rate of three per cent. for the quarter, with a bonus of two per cent.

At the annual meeting of the Peterson Lake the following board of directors was elected:—Sir Henry M. Pellatt, Major Murray, Hugh Blain, W. F. Scott and A. M. Hay. With this new board it is to be hoped that there will be no more quarrelling and that the directors will get down to business.

It was pretty generally expected that when the camp was supplied with cheap power a great increase in mining activity would be the outcome, but so far this has failed to materialize. One feature however is the very much lower cost of concentrating, which in the case of the McKinley-Darragh, is now only $1.30 a ton, while at one of the larger mills the management expects to be able to treat for about $1.00 a ton. This of course is only about fifty per cent. of the milling costs of a year ago, and permits of the treatment of much lower grade ore.

The returns from ore royalties paid to the T. & N. O. Railway Commission for the month of March amounted to only $375.00. This is a great falling off from the previous year, and is partially due to all the companies, with the exception of the Right of Way, paying 25 per cent. of the net profits instead of the gross returns as formerly.

A deputation of local mining men waited on the Hon. Mr. Cochrane with a view to getting an extension of time for the performance of work on the claims staked on the iron deposits near Grand Rapids. As the district is over eighty miles from a railroad, and the trip is very hard, the Minister promised to allow them ample time.

The Crown Reserve has declared the regular quarterly dividend of six per cent., with a nine per cent. bonus. This is payable July 15th. The payment of dividends at this rate means that the shareholders are receiving practically $3,000 a day. This property has already paid and declared 120 per cent. on its capital of $2,000,000.

The shaft of the Bailey is now down 160 feet, and at that point a station is being cut. A cross-cut will be run to cut several small veins that are showing in the tunnel. Another will be driven about 200 feet in an effort to locate the Bailey vein.

Porcupine.—The transportation facilities into this district are very bad, and it is believed that they will eventually lead to a shortage of supplies. Provisions are quite scarce now, and prices are very high, and there appears to be no immediate prospect of their bettering. This condition is partly accounted for by the larger number of men employed than was anticipated, and also by the early break up, which destroyed the roads a full month ahead of the usual time. Although active representations have been made to the Government to construct a road, and there is no question of the needs of the district, work was only started a short time ago. A small sum of money has been voted, and some prisoners from the North Bay jail are to be sent up to cut out the road. Several good discoveries have been reported lately, two of which are on the Reserve. On the silver properties a good vein was uncovered, and another strike was made on the Novak claim. A Boston syndicate has taken options on over fifty properties in Tisdale. These claims are owned by several people, but they are in almost a solid block. On about twenty of these good showings are reported. It has been decided to start work again on Gold Island, in Night Hawk Lake, the first property in the district on which work was done. A number of surveyors are in the bush running out the lines for twenty-seven new townships. The boundaries of the mineralized area have become so extended that it is necessary to have new points to which to tie the claims. On the Timmins property the small stamp mill will soon be erected and running, and will be used to treat the ore that comes from development work. By this means the owners will gain a much better idea of the average value of the vein. Negotiations are under way for the purchase of several claims, and there is a great deal of activity throughout the camp. It is stated that there will be twenty-four companies operating during the summer that will spend a minimum of $15,000 each. It is stated that a contractor has offered to grade a line into Porcupine from mile post 222 on the T. & N. O., for $10,000 a mile. This would be only for the grading, and the Government would have to lay the steel and put the line in shape. It is very doubtful, however, if the matter will be taken up. A couple of lines of boats are now operating, so that accommodations for travellers have much improved. There appears to be a renewal of interest in the finds in Bryce Township, and some good finds have been reported lately. The Martin claims have been purchased by a Montreal company known as the Thelona Gold Mines Co. and work is to be started immediately. The property consists of six claims, and on the principal vein a number of test pits are to be sunk. In order to gain as much information regarding their properties in the shortest possible time the Dome Mining Company is sending in two diamond drills. Some very high grade ore is being produced, and high grading has become so common that it has been found necessary in some instances to employ guards.

South Lorrain.—A party of Buffalo men has lately gone into the district to look over several claims with a view to purchasing. It is a peculiar fact that fully two-thirds of the capital invested in this section is from the city of Buffalo. On the Fuller properties surface trenching has uncovered ten veins. These are largely calcite and cobalt, with low silver values. Another new company, known as the Alice Lorrain Mines, with a capital of $500,000, has been formed. Its headquarters are Haileybury. At the annual meeting of the Maidens, recently held, the old board of directors was re-elected. The report on the conditions prevailing at the mine was satisfactory, and there is talk of putting in a new plant. Despite the handicap of bad roads throughout the district, things are progressing favourably, and there will be a large amount of work done this summer. The Mines Power Company expects to have its installation completed about the end of July, and this will very naturally help the district. The new power driven compressor for the Wettlaufer is still lying at the wharf, and on account of the bad roads there is no immediate prospect of getting it to its destination. Negotiations are under way for the purchase of the Beaver Lake property. Just before it shut down, for lack of power, silver was struck in the drift at the 110-foot level. The price asked is about $300,000. The Mayflower Company has started a gang of men to work surface prospecting. Several promising veins have been found in the vicinity of this property. It is reported that Buffalo people have taken an option on a sixty per cent. interest in the Little Keeley, which adjoins the Haileybury Frontier. Last year a promising vein, carrying silver values was discovered. A shaft has been sunk some distance on another vein, but with this exception little work has been done. The Montrose company is pumping out the shaft preparatory to resuming underground operations. A promising vein has been traced from the Harris property adjoining, and shows considerable bloom with low values in silver.

GOWGANDA.

This season's work has already been productive of excellent results, and has helped to demonstrate the fact that the district shows every promise of becoming one of the important silver mining camps in New Ontario. Unlike Cobalt the area is of large extent, and there are many groups of mines scattered over a large territory. At the Bonsall property ore was discovered at a depth of 110 feet in the shaft, and at 140 feet the vein was carrying about 4,000 ounces in silver. The Hudson Bay Mining Co. of Cobalt is working two properties, one near Lost Lake and the other at Hanging Stone Lake, and good results are reported. The Rawhide property has good ore, but has been forced to practically suspend operations underground until a plant is installed. Excellent discoveries have also been made near Calcite Lake. At Maple Mountain a good find has been made on the Devine properties near Skull Lake. The vein was in one place twelve inches wide, and carried high values in silver. This section has never received much attention in comparison with other places, but is being quietly developed with satisfactory results. The extension of the Morrison vein is stated to have been cut at the 100-foot level of the McKay property, where it shows considerable high grade ore. The Silver Alliance at Elk Lake is reported to have sunk a small test pit on a new vein and opened up some rich ore.

BRITISH COLUMBIA.

The quantity of concentrate and crude ore shipped from the St. Eugene Mine, East Kootenay, to the Consolidated M. and S. Company's smeltery at Trail during four months ended April 30th was 5,860 tons. The greater part of this was lead-silver concentrate—approximately 5,000 tons.

The report that the North Star Mine had been sold to the Consolidated M. and S. Co. has been contradicted. Officials of the company state that, so far as they know, there have not been any negotiations for its purchase.

The Silver King Mine, near Nelson, has been closed, owing to difficulties experienced in keeping the water down so as to allow of ore being mined below water level. Operations have latterly been unprofitable, so the Kootenay Development Syndicate, which was working it under lease, is not likely to do anything more on it.

The British Columbia Copper Co. has commenced to ship ore from its Wellington group mine to its smeltery at Greenwood, the railway spur to the mine having lately been completed. The same company is now in charge of operations at the Rawhide and other New Dominion Copper Co. mines, in Phoenix camp, following the purchase of a controlling interest in the latter company.

The old City of Paris Mine, situated south of Phoenix Boundary district, near the International Boundary line, will probably be prospected with a diamond drill shortly. In the early nineties approximately 7,000 tons of ore of good grade was shipped from this mine to the Granby Co.'s smeltery, but on the ore shoot becoming exhausted, operations were suspended and the mine has since remained closed.

Mining has been resumed at the Queen Victoria Mine, near Nelson, and ore is again being sent to the smeltery after about eighteen months inactivity. The ore is copper-gold and occurs in large quantity.

Swede Group, Poplar Creek.

Another effort is being made to test the value of mineral claims at Poplar Creek camp, which is near the boundary between the northern part of Ainsworth mining division and the adjoining Trout Lake division. A Scottish syndicate has taken an option on this property, which in 1903-4, when there was much local excitement concerning finds of rich surface specimens of free gold on the Swede group, Lucky Jack, and other claims, was regarded as one of the best in the camp. The syndicate referred to is represented in the province by Mr. W. J. Anderson, who has already been two months in the district, and has let a contract for driving 300 feet of tunneling, and good progress is being made with this prospecting work. It is stated that Mr. Anderson intends remaining in the district until next October, and that his principals will bond other mining properties should the results of the work undertaken on the Swede group be considered satisfactory.

In the Lardeau.

The Silver Cup Mine, owned by the Ferguson Mines, Ltd., is again being worked, after having been closed temporarily, owing to the great difficulty of getting supplies up to the mine during the depth of winter. This mine last year shipped to the Consolidated M. and S. Co.'s smeltery at Trail 1,631 tons of high-grade silver-lead ore, which also contained some gold. The Silver Cup group consists of nine mineral claims, situated on the north slope of Silver Cup Mountain, south of the south fork of Lardo Creek, and distant from the Town of Ferguson about six miles in a direct line. The altitude of the mine is 6,500 to 7,000 ft. above sea-level. The ore occurs in two leads striking nearly parallel to the formation. The northern lead is called the Silver Cup vein, and the southern one the blind lead, the latter not being exposed at the surface. Between the leads are cross fissures, one of which made a large shoot of ore. The ore body usually consists of a number of veins of quartz; the ore being localized in shoots, lenticular in form both horizontally and vertically. Some of these are of comparatively large size, one continuous stope being 275 feet in length. The quartz is usually heavily mineralized with grey copper, galena, blende, and some copper and iron pyrites. It seems evident that mining operations have been and continue to be profitable, for they have been carried on, with but little intermission, during about 14 years.

Improved Prospects for Kamloops Camp.

It has been learned on good authority that the sum of $100,000 has been appropriated for the development of one metal mining property in Kamloops camp, and that there is reasonable probability of others being worked, as well.

Of one part of Kamloops camp, the following was written a few months ago: "Generally speaking, it may be said that south of Kamloops Lake, between Cherry Creek and about three miles east of Kamloops, there is an area of ore-bearing rocks extending some eight miles along the shore of the lake, and four to six miles south from it. The extent of surface mineralization, as regards copper, is considerable over a large part of this area. Taking the camp as a whole, however, the great mass of ores occurring in it is of too low a grade to admit of its being shipped to outside smelteries, unless extensive development shall prove that below the surface the average grade of the ore is much higher than has been demonstrated in that occurring nearer the outcrops. With its really immense mineralized areas, the district amply warrants much more investigation in the way of mining development than it has yet had. Its great extent, however, will involve a large expenditure before it will have had the thorough examination necessary to determine its general value. It offers advantages, though, for making it a smelting centre, conditionally, of course, that thorough development of its mineral claims shall warrant that being done. Among these advantages are its proximity to the Nicola Valley coal fields, which would most likely supply metallurgical coke of good quality, and the fact that within a few years Kamloops will be the meeting place of two or three transcontinental railways. Keeping in mind the several favourable factors, it may be concluded that Kamloops may yet become one of the important mining and smelting centres of British Columbia.

Emissions Minieres, Ltd.—A French company, named the Emissions Minieres, Limited, having offices in England, intends working the Joker Mine, situated in what was formerly known as Camp Mansfield, at the headwaters of the south fork of Kaslo Creek. Work was done in this camp about ten years ago, but since that time the claims have been allowed to remain unworked. Much money was spent on this property, but without profitable results to the former owners. The new company has appointed Mr. A. Fournier to superintend the installation of a power plant on or near the Joker claim, and to drive a tunnel an estimated distance of 800-ft. with the object of cutting the vein at a depth of between 300 and 400 feet. The machinery to be put in consists of a 5-ft. Pelton waterwheel and a Fraser & Chalmers 16 by 18-inch belt-driven air compressor, with the usual complement of accessories. The air compressor is designed to supply sufficient air to drive three machine drills. It is expected to shortly be received at Kaslo from England. Provision has been made for its enlargement should more power be required later. The Pelton wheel is already at Kaslo, whence it will be transported to the mine as soon after the Provincial Government road men shall have repaired the wagon road up the creek as shall be found practicable. The distance between the railway and the Joker mine is about 18 miles. There will also have to be taken up to the mine 1,500 to 2,000 feet of 10-in. pipe through which to convey water to the wheel. It is estimated that ,with the 500-foot head available, from 600 to 800 horse-power will be developed by this wheel. There will hardly be sufficient time after putting in the machinery to do much development work before next winter, but it is hoped a start will be made at driving the adit, and all necessary supplies have been taken up to the mine to admit of operations being continued throughout the winter, during which period no communication can ordinarily be made with the mine, owing to its high altitude. The enterprise of the company is a plucky one, and merits success, but it is by no means sure that this will result, although it is known that ore of good value occurs in Camp Mansfield properties.

Slocan Mines Near Sandon.

Steady progress is being made at several of the mines in the vicinity of Sandon, Slocan district. Among the number are the Ruth-Hope, Slocan Star, and Richmond-Eureka groups, in the immediate neighbourhood of Sandon, and the Surprise, Noble Five, and Sunset, above Cody.

There is in the Ruth Mine a lot of milling ore ready for stoping, and preparations are being made to start the concentrator for the season's run on ore from this mine. Last year's output from the Ruth-Hope Mines was nearly 1,000 tons of silver-lead ore and concentrate, shipped to the smeltery at Trail, and 655 tons of zinc-silver concentrate sent to the United States.

The showing of ore in the Hope No. 4 tunnel, known locally as Malcolm's tunnel, is an excellent one, and from this shipments will shortly be made. The deep wash has been sluiced off the hillside below the portal of No. 4, and the vein exposed at a vertical depth of approximately 200 feet under that opening. The driving of an adit on the vein at this lower level will shortly be commenced, and this will provide another face from which to take out ore and, as well, admit of opening new stopes.

The Slocan Star mine, owned by the Byron N. White Company, and the Richmond-Eureka, by the Consolidated Mining & Smelting Company of Canada, are being worked so far as the Nos. 5 and 6 tunnels of the latter and the Slocan King tunnel of the former, under an arrangement mutually advantageous. Both Nos. 5 and 6 were started on the Eureka claim and passed thence into the Hidden Treasure claim of the Slocan Star group. No. 5 crosses one corner of the Hidden Treasure passing thence again into Richmond-Eureka ground. No. 6 is on the Eureka for about 500 feet, and has been extended a similar distance into the Hidden Treasure. At 1,200 feet from its portal it will enter the Consolidated Company's Summit claim. In Hidden Treasure ground an incline raise is being made in the vein from No. 6 to No. 5, a distance of 170 feet, rather more than half of which has been driven. It is expected this raise will be through to No. 5 early in July; thereafter the driving of No. 6 to the boundary of the Hidden Treasure will be proceeded with, and then the Consolidated Company will take up the work of its further extension so as to develop the Summit claim at that level. The adit opened on the Slocan King at about 200 feet below No. 6, is in approximately 1,600 feet on the vein, and is now in the Hidden Treasure. Three shoots of ore have been passed through, and it is expected another shoot, opened in Nos. 5 and 6 above, will be reached at 200 feet farther ahead. The chief purpose now is to get No. 6 and the King tunnels well into the mountain so as to cut on their downward extension several ore-shoots found in No. 5 and believed to go down, and to make raises in them so as to provide good ventilation. After this shall have been done the miners will be set to work cross-cutting from these main adits at several places where such work shall be deemed likely to lead to the finding of other shoots of ore. Stopes will be opened in the ore shoots and all ore of sufficiently good grade will be shipped to the smeltery. A baby tram is to be constructed from the portal of No. 6 up to the upper terminal of the aerial tramway from No. 5 level down to the railway in Sandon, the distance between the two portals being 500 feet. This will be a single-bucket tram, with one stationary and one hauling cable. The latter will be wound round a drum at the top attached by gearing to the main tramway, which will provide the power necessary to haul the ore up from No. 6 for both companies. As practically all the shipping ore from the above-mentioned workings will be of suitable grade for shipment crude to the smeltery, it is improbable the Slocan Star concentrating mill will be operated this season, not unless work shall be resumed in the older parts of the mine which were closed several years ago following extra lateral rights litigation, happily now settled.

On the several Cody properties already mentioned development work is being continued. The deep-level tunnel by which the Surprise is being developed is an extension of the Last Chance tunnel. It is a long cross-cut, and enters the Surprise vein at a depth of about 1,100 feet below the surface workings of that mine. The old workings of the Surprise are down about 300 feet, so a raise has to be put up 800 feet to make the necessary connection. About one-third of this raise has been driven, but the work is necessarily slow and difficult. Some good ore

has been met with, but no stoping will be done until after the raise shall have been put through and proper ventilation thereby provided.

No. 8 tunnel of the Sunset group is now in about 520 feet, and the vein should be reached in 50 to 80 feet further. It will then be necessary to drift something like 500 feet in order to get into the ore shoot worked in No. 7 at a vertical distance of 246 feet above No. 8. Indications show that another shoot of ore should be encountered before that going down from No. 7 shall be reached. The portal of the tunnel is out of the way of snow-slides, so that there is no danger to men going to and fro when the snow lies deep above it.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

There was a further heavy decrease in the coal export trade of South Wales in May. This to some extent was contributed to by the fact that May contained one less working day, owing to the funeral of the late King Edward. Apart from this, however, the decrease in all respects is very disappointing, and it is quite clear that at least up to the end of the past month the coal trade had failed to throw off the serious after effects of the dispute in the coal-field. At Cardiff shipments in May totalled 1,411,770 tons, or a decrease of 123,364 tons on May of 1909. Newport, also accounted for a heavy falling-off, namely, 125,678 tons. This was largely due to the dispute of the general cargo workers and employers, resulting in a temporary stoppage of the whole of the dock workmen and the fears of shipowners that a prolonged strike would take place, and also the diversion of tonnage to South Wales ports which was resorted to in consequence. Swansea accounted for a decrease of 28,146 tons, but Port Talbot, unlike the other ports of South Wales, continues to retain the record of the preceding months of the year, and again shows an advance of 32,427 tons.

The shipments of Cheshire salt for the month of April, as disclosed in the official return prepared by the Salt Union, reached the comparatively large total of 39,418 tons, as against 30,318 tons a year ago, while the coastwise trade reached 12,539 tons, as against 6,530 tons, the total increase being slightly over 15,000 tons. In the foreign trade the chief improvement is with Calcutta, the increase being 9,000 tons, while in the home trade Scotland has taken 10,503 tons, as against 4,918 tons last year. There has also been a substantial improvement in the exports to Denmark, and in other directions trade was normal.

FRANCE.

The technical commission appointed by the British, French, German and Spanish Governments to draw up a scheme of mining regulations to be applicable to Morocco for submission to the Diplomatic Body at Tangier has concluded its labours, having agreed upon the terms of its report.

AUSTRIA.

In view of the resumption of the Petroleum Conference at Vienna, the Austrian Government is bringing pressure to bear on the Standard Oil Company in order to induce the latter to come to terms with the refiners in the dual monarchy and abandon the campaign of price-cutting in kerosene and other products.

Two of the points singled out by the Government for attack will probably be the quantity of oil refined by the Standard Oil Company—which is asserted to have been last year largely in excess of that for which it is licensed—and the system of tank-wagon delivery directly to the private consumer, which the Standard Oil Company has brought to a high pitch of organization.

Another well on the Tustanowice field has struck oil—the Dlugoza well No. 4, which is yielding 60 tons a day, estimated to be worth over £80.

UNITED STATES.

New York City, June 18th.—The reports of the Greene Consolidated Copper Company and the Cananea Consolidated Copper Company for the year 1909 have been made public. The latter company, whose stock is owned by the former, shows a slight increase in the cost of producing copper last year as compared with that of the previous year. The cost of mining was $2.22 a ton, as against $2.13 for the previous year and $3.28 a ton for the 15 months ended October 31, 1907. Of this sum of $2.22 nine and one-half cents per ton consists of improvements and equipments installed charged off during the year. This is most satisfactory, the report says, for the reason that the extra money spent in development has amounted to at least 20 cents per ton over the same cost the year previous, and for the reason that there has been a greater proportion of smelting ore mined in the new mines, where cost is necessarily higher. Copper production costs were 11.64 cents per pound, as against 10.51 cents in 1908. The average selling price was 13.11 cents.

New York City, June 15.—The report of Jay P. Graves, vice-president and general manager of the Granby Consolidated Mining, Smelting & Power Company, to the directors of the company, apparently is of such a nature that they do not care to make it public. The Granby board has just held its second meeting since Mr. Graves submitted his report on the condition of the property, and the statement was made after the meeting that no business of public interest was transacted.

Boston, Mass, June 18.—The Utah Copper Co'y is now earning from the operations of its own properties $3.13 per share on its enlarged capital, against $3 being paid. This is on the basis of 12 1-2 cent copper. The company therefore may regard as "velvet" the $1,425,712 derived from its ownership of 950,476 shares of Nevada Consolidated stock, which is paying dividends of $1,500,000 a year.

Spokane, Wash, June 15.—Reports compiled by the statistical department of the Spokane Chamber of Commerce show that mines in the Coeur d'Alene district in northern Idaho have produced ore of a total gross value of $192,455,691 since the discovery of the placer ground late in 1882, and that, including the June disbursements, a total of $39,391,200 has been paid in dividends, as follows: Bunker Hill & Sullivan, $11,737,200; Standard-Mammoth, $9,000,000; Empire State, now Last Chance, $4,750,000; Hercules, $3,750,000; Morning, $2,000,000; Hecla, $1,970,000; Snowstorm, $1,300,000; Tiger-Poorman, $1,250,000; Granite, now Success, and Gem, $500,000 each; Hunter, $250,000; Sierra Nevada, $225,000; Pittsburg Lead, $200,000; Caledonia, first dividend paid April 25, 1910, $39,000; other gold mines, estimated, $600,000.

Against this net earning there is chargeable as an offset approximately $2,376,000 for 30 miles of non-productive development work. This shows that $19 has been earned in actual profits for every dollar assumed to have been lost in opening new properties in the district.

Goldfield, Nev., June 14.—Despite its materially reduced mill capacity the Consolidated Mines Company is maintaining earnings upon a basis insuring its ability to continue dividend payments at the rate of $2 per share annually. Immediately after the fire in the mill on April 8 officials of the company declared that no interruption in dividends would result and that earnings would continue at the rate of approximately $700,000 monthly.

The report of Manager J. R. Finlay for the month of May shows that the net profits of that month have been surpassed in only three prior months of the company's history. The tonnage mined was above the average and total costs were still somewhat high owing to the charge for mill reconstruction.

The mill treated during May an average of nearly 640 tons daily

and all repairs will be completed before the end of the current month. Ten additional stamps, which were only slightly damaged, have been placed in commission, making 80 now operating. The gross value of ore mined in May was $1,021,656, the total costs and losses $298,260, and net profits $723,396.

Parker, Ariz., June 18.—The old Planet mine is making good. According to the predictions of Dr. Harvey Weed, a large body of ore has been encountered in prospecting with churn drills.

Years ago this mine was made famous by the thousands of tons of high grade copper ore that was taken by primitive methods from the surface workings and shipped to Swansea, Wales, for treatment.

Los Angeles, Cal., May 28.—The Ventura oil fields are the centre of wide interest as a result of the steadily increasing demand for the high-gravity petroleum of this section. Approximately 40 strings of tools are in commission and dozens of new derricks are in course of erection. The product for April was about 20 per cent. in excess of the March yield, and the demand for the high-class oil has stimulated developments to a tremendous extent. In order to overcome the difficult transportation problems that have been the chief cause of holding back the district the Sagan-Loomis Company has placed in commission a 40-ton traction engine and two 10-ton wagons. These will facilitate the rapid and economical shipment of supplies and enable operations to be conducted along more rapid lines. The district is very hilly and the transportation question has been an important one.

MEXICO.

Evidence of the progress of the oil industry in Mexico is afforded by the news that early in May a tank steamer received, from the Oilfields of Mexico Company, whose property is situated at Finbero, in the State of Vera Cruz, a shipment of 22,000 barrels, equal to 924,000 gallons. The oil was passed through a pipe line from Finbero to the receiving tanks of the Eagle Company, which was floated in this country by Sir Westman Pearson a few weeks ago. The receiving tanks are some 60 miles from the fields, and are connected with them, both by railway and pipe line. After using the pipe line for the first shipment, early in May, it was found to be defective, but it has since been thoroughly tested and is now in perfect working order. Oil is now being pumped into the tanks at Tuxpan, and it is expected that regular shipments will now be made, another tank steamer being due to be loaded within the next few days.

SOUTH AFRICA.

As the April crushing returns from the Witwatersrand Mines exhibited an improvement upon the March figures, so do the results of May show an advance upon those of April, only in a greater degree. The aggregate profits of some fifty-five mines in May reached £966,000, as compared with the April figure of £938,000, and £923,000 in respect of March. If the results of one or two minor undertakings be included, and also those of concerns which operate in other sections of the Transvaal goldfields, the million pounds sterling mark would be passed for the first time this year. This attainment is all the more noteworthy when it is recalled that during May for various reasons more than one important mine had either to hang up a portion of its mill or to entirely suspend crushing for a time. Despite this fact, the ratio of operating costs as a whole shows no increase, and a small improvement in the mill grade is accordingly reflected in an increased profit per ton. Well over a score of the companies earned higher profits in May than during any other month this year, amongst them being four of the Rand Mines group.

Company Notes.

Notice is given that a quarterly dividend of 1 3-4 per cent. on the preferred shares of the capital stock of the Amalgamated Asbestos Corporation, Limited, has been declared payable on July 1st, 1910, to shareholders of record June 20th, 1910.

At the monthly meeting of the Board of the Lake Superior Corporation, held in New York June 22nd, the executive reported satisfactory earnings for the past month, and also for the ten months ending April 30th.

The president reported that, in pursuance of the present policy of the executive of making the steel department independent in regard to its requirements for raw materials, the Connelton Collieries in West Virginia have been purchased; the property consisting of about 6,000 acres and now producing about 1,000 tons of coal of high quality per day. The purchase was unanimously approved by the Board.

The steel department, through this purchase of coal properties and recent developments in iron ore properties on the line of the Algoma Central Railway, and through the securing of extensive limestone areas, is now fully assured of a practically unlimited supply for its necessities in raw materials.

The delivery of the Connelton Collieries as a going concern will be taken on July 1st next, and new machinery will be installed to double the present output, and further increase will be made in output as found necessary. The coal property carries three seams of high quality, and will be operated by a subsidiary company, which has been incorporated in West Virginia as the Connelton Coal & Coke Company; the stock being owned outright by the Lake Superior Corporation.

Good progress was also reported in connection with the construction of the Algoma Central Railway and of the new coke oven and by-product plants, rolling mills, blast furnaces, etc., at Sault Ste. Marie.

DOMINION IRON & STEEL ANNUAL MEETING.

The annual meeting of the shareholders of the Dominion Iron & Steel Company, Limited, was held on June 17th in the Bank of Commerce Building. Mr. J. H. Plummer, as president, was voted to the chair, and, after a few formalities, he presented the annual report, which has already been published.

In discussing the report, he reviewed at some length the events of the year in connection with the company. He referred to the purchase of the fifty thousand shares of Dominion Coal Company, and pointed out that, though there might be some criticism on the part of a few shareholders as to the deal, it must be remembered that when a thing is wanted, "you have to pay the price."

Mr. Plummer stated that the bounty on pig iron will cease in December next, and that on wire in June of next year. To make up for this he had every reason to believe that at the next session of Parliament increased protection would be given.

The new works of the company, such as the ovens, machinery, finishing mill and others will be ready in the near future, and it is the intention of the management to build new shops and foundry.

Mr. Plummer then referred to the various exceptional expenditure of the year, such as the $160,000 above contract price which they had to pay for coal, and the $300,000 loss in the battle with the Coal Company. The consolidation of the interests was, however, a source of great satisfaction all round, and was, of course, the feature of the year. It was also a matter of congratulation that the company holds ninety per cent. of the shares of the two companies. He said, with a smile, that if there are any shareholders holding out for an increased offer they will be disappointed, as the ninety per cent. is very satisfactory. The consolidation of the two companies removed all chance of trouble, and a bright future was looked forward to.

Resolution of thanks to the president, directors, management and employees were passed and responded to and the following board of directors was re-elected:

Sir H. Montagu Allan, George Caverhill, Hon. George A. Cox, H. F. Dimock, Hon. L. J. Forget, Hon. Robert Mackay, Hon. David MacKeen, William McMaster, Frederic Nicholls, J. H. Plummer, Elias Rogers, W. G. Ross, and Sir William Van Horne.

STATISTICS AND RETURNS

LA ROSE PRODUCTION.

The properties of the La Rose Consolidated Mines Company during the fiscal year ending May 31, 1910, produced 3,125,000 ounces of silver, compared with 3,010,831 ounces for the previous year.

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending June 17, and those from Jannuary 1, 1910, to date:

	June 18. Ore in lbs.	Since Jan. 1. Ore in lbs.
Beaver	.....	120,450
Buffalo	80,000	963,368
City of Cobalt	.....	363,835
Chambers-Ferland	118,480	589,300

Nipissing	367,670	4,923,797
O'Brien	.....	648,046
Peterson Lake	.....	330,710
Provincial (Govt.)	.....	65,000
Right of Way	.....	757,257
Silver Cliff	.....	117,510
Temiskaming	60,000	741,830
Trethewey	.....	503,950
Waldman	.....	63,992

Ore shipments for the week ending June 17 were 1,692,350 lbs., or 846 tons.

Total shipments from January 1 to June 17 were 27,393,483 lbs., or 13,696 tons.

Another unusually heavy output of ore from the Cobalt camp is recorded this week. Eleven mines are named in the list and they shipped during the week 1,808,869 pounds, or 904 tons. The feature of the shipments was Nipissing's consignment of 483,540 pounds, thus heading the list. The Kerr Lake property continues to ship largely, being second in the list this week, with 470,159 pounds. La Rose came third, with 272,790 pounds of ore. Both Chambers-Ferland and Crown Reserve sent out over 124,000 pounds each. The total shipments from Cobalt to date since January 1 are 14,601 tons.

Cable Address: Halharding, New York. Code: Bedford-McNeill.

MEN OF WEALTH

Are almost invariably the greatest believers in Life Insurance because they recognize the value of a "Cash" estate absolutely secured, and therefore they aim to maintain a considerable portion of their estate in the form of Life Insurance.

The North American Life Assurance Company appeals to business men because of its long record of success and its able and progressive management.

Assets, over $10,500,000. Net Surplus, over $1,000,000. Good Agency openings for energetic men.

PROSPECTOR'S OUTFIT—FITTED WITH

NISSEN STAMP MILL

A practical outfit for prospectors—one that is easily taken apart for transportation, and that can be used as a unit in a larger plant should your claim make good. One man is all that is required to operate the outfit. A FAIRBANKS-MORSE gasoline engine furnishes the power. Nissen Stamps are conspicuous for their large capacity and small power consumption. Descriptive pamphlets upon request.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

GEOLOGICAL SURVEY

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, and with many local areas and special subjects.

MARITIME PROVINCES

The whole of Cape Breton, and a large portion of the coal and gold fields of Nova Scotia, have been reported upon, and mapped on a scale of 1 mile to 1 inch. The remaining portions of the Province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter Provinces, mapped on a scale of 4 miles to 1 inch.

QUEBEC

Quebec, south of the St. Lawrence, has been reported upon, and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the Province north of the St. Lawrence are also available.

ONTARIO

A large part of the Province of Ontario, more particularly the northern and western portions, has been reported upon and mapped

THE PRAIRIE PROVINCES

Geological maps and reports have been issued covering the greater part of the Provinces of Manitoba, Saskatchewan, and Alberta

BRITISH COLUMBIA

The southern portions of British Columbia, as well as other parts of the Province, have been reported upon and mapped.

YUKON

Many of the important areas in the Yukon have been reported upon and mapped.

THE NORTH WEST TERRITORIES

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of a report or map will be sent to Canadian applicants free of cost, and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

Applications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.

THE FOLLOWING GEOLOGICAL MAPS HAVE RECENTLY BEEN ISSUED:

CANADA

1084. General Geological Map of Canada. Scale 100 miles to 1 inch.

NOVA SCOTIA

1019. City of Halifax Sheet.
1025. Waverley Sheet.
1037. Windsor Sheet.

The above sheets belong to the regular series of Nova Scotia map sheets on a scale of 1 mile to 1 inch. The first includes Halifax City and Harbour, the second the Waverley Gold District, and the third Gypsum Quarries.

ONTARIO

1023. Geological Map showing position of Corundum-bearing rocks in Central Ontario.
1076. Gowganda Mining Division.

This map besides representing the geology of the Gowganda area, represents the geography of a considerable area to the east and north.

980. Portion of Algoma and Thunder Bay districts, Ontario, 1908. W. J. Wilson.
1081. Region lying north of Lake Superior between the Pic and Nepigon Rivers, Ontario, 1906. W. H. Collins.

BRITISH COLUMBIA

1002. Geological Sheet, Special Map of Rossland.

This map, on a scale of 400 feet to 1 inch, besides accurately indicating the topographical and cultural features, shows the geology and location of veins.

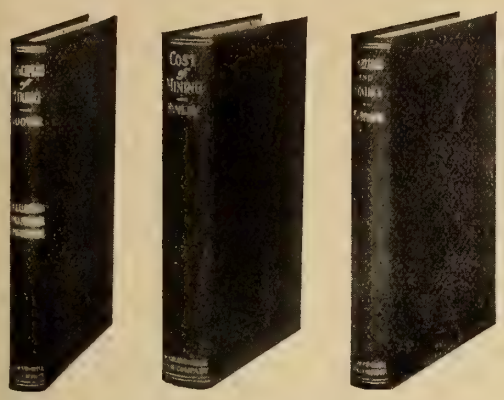
1004. Geological Sheet, Rossland Mining Camp. Scale 1200 feet to 1 inch.
1074. Sketch map of Sheep Creek Mining Camp, West Kootenay, B.C., scale 1 mile to 1 inch.

YUKON

1041. Geological and Topographical Map of Whitehorse Copper Belt. Scale 1 mile to 1 inch. Also several detail maps of same belt

NOTE.—Maps recently published may be had on linen cloth, for use in the field, at 10c. per copy.

REPORTS



1072. Summary Report of the operations of the Geological Survey for year 1908.
1085. Descriptive Sketch of the Geology, and Economic Minerals of Canada. G. A. Young. Introduction, R. W. Brock.
1075. Gowganda Mining Division, 1908. W. H. Collins.
1035. Coal Fields of Manitoba, Saskatchewan Alberta, and Eastern British Columbia, 1908. D. B. Dowling.
1050. Whitehorse Copper Belt, Yukon. R. G. McConnell.

NEW CATALOGUE

1073. Catalogue of Publication 1843—1909.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

The Three Most Important Mining Books of Recent Years

They Cover

PRINCIPLES—ECONOMICS—METHODS

Principles of Mining. By H. C. Hoover, $2.50 (10/6) net postpaid.

The principles of mining as developed by modern science and business methods are here fully discussed under the general headings of Valuation, Organization and Administration. Important chapters cover investment from the public's standpoint, and the character, training and obligations of the mining engineer.

Cost of Mining By James R. Finlay. $5.00 (21s) net, postpaid.

An economic investigation of the cost of scientific. profitable mining. It contains valuable data obtained from official reports of the mines producing 75 per cent. of the metal under discussion. Detailed analyses cover cost of mining *coal, iron, lead, zinc, copper, gold and silver.*

Timbering and Mining. By W. H. Storms, $2.00 (8/6) net, postpaid.

Deals with practical methods, not theories. A straightforward account of the best, safest and most economical methods employed in the leading American mines.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are: Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows:

All mines belong to the Goverment of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unserveyed territory, is open to prospecting.

Miners' Certificates good for a calendar year may be obtained by sending $10.00 to the Department of Mines. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minium being 40 acres in unserveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of $10.00 plus a yearly rental of $1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed territory may be purchased as a mining concession at the price of $20.00 per acre if within 20 miles of a railway in a straight line, or $10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

The Hon. Minister of Colonization, Mines and Fisheries.
Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

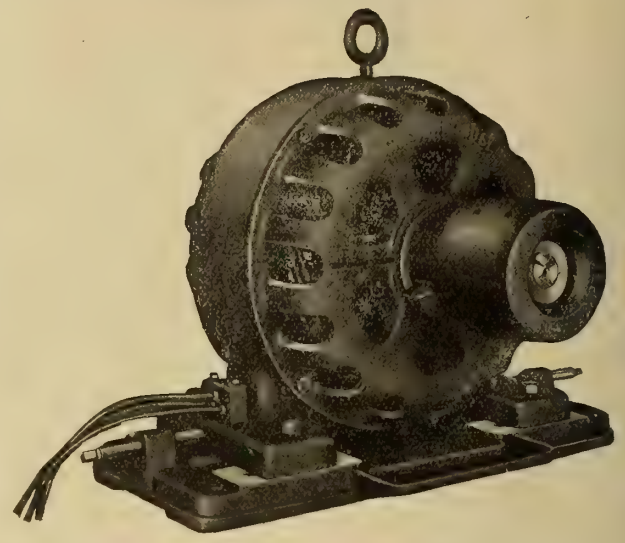
Westinghouse

Type "CCL" Induction Motors



The only wearing parts of Type "CCL" Motors—the bearings

are designed and constructed to withstand years of the severest service without other attention than an occasional filling of the oil wells.

On motors above 5 horse power capacity the bearings are split, the interior of the housing forms the bearing shells which are lined with a special grade of bearing metal, the bearing housings are clamped between the halves of the bracket and are held in perfect alignment with each other by dowel pins.

On motors below 5 horse power capacity the bearing housings are cast solid with the bracket, and the bearings are bronze bushings pressed into place and pinned.

Each split bearing has two oil rings; the solid bearings one. The lower part of the housing forms an oil well from which oil is carried by the rings to the top of the shaft and distributed through grooves to all parts of the bearing, thus keeping it flooded with oil while the motor is in operation. **Ask nearest office for Circular 1118. It tells all about Type "CCL" Induction Motors.**

Three Post Magneto Electric Blasting Machine

NOBEL GELIGNITE

It always breaks cleanly to the bottom of the drill holes and is free from fumes of any kind. Equal to 75% Dynamite and is sold at a price producing very much better results in terms of Rock Broken or Extracted and money spent.

"WINTER BRAND" DYNAMITE

Is only one strength, if anything, a little stronger than 50% Dynamite. **It does not freeze,** or rather, explodes with perfect efficiency when frozen **and needs no thawing.**

"AUTUMN BRAND" DYNAMITE

Is packed in all the usual percentages. The powder is similar in appearance, character and effect to ordinary Dynamite, except that the freezing temperature of the Nitro-Glycerine is reduced from 42° F to a little under 30° F.

PERMITTED EXPLOSIVES for Coal Mines
Nobel Monobel, Saxonite and Carbonite.

BELLISS ENGINES

Have won the approbation of the well informed engineers of Canada: not only the theoretical man, but the practical Commercial Engineer, who has the spending of the money.

When the Engineer has a reputation for safe Engineering to maintain, why does he recommend the Belliss Engine?

BECAUSE—

It is absolutely reliable.

It will go right into service when started up; all its finishing and adjustments having been made in the builders Works.

Its running is ceaseless, noiseless, "cost less."

The first engine of the type built 20 years ago is still running 625 r.p.m. day in and day out all the year round and shows no sign of wear.

Is it surprising that Belliss Engines have been installed by such leading firms, institutions and Cities as Dominion Iron & Steel Co., Canadian Locomotive Works, Dominion Bridge Works; Universities of McGill, Toronto, Queens, Saskatchewan; Cities of Montreal, Edmonton, Lethbridge, Westmount, Verdun, Brockville, Renfrew.

Builders: Belliss & Morcom Ltd., Birmingham, England.

Canadian Agents: Laurie & Lamb, Engineers, Board of Trade Building, Montreal.

"CLEVELAND" STOPE DRILLS

EFFICIENCY:—Of course you want the stope drill which has the highest efficiency, but you must pick out the one that will have as high an efficiency a year from to-day. Isn't it true that your stope drills decrease steadily in efficiency as they grow older?

REPAIRS:—Repairs which must be made from time to time after the part has given long and satisfactory service, are not a source of dissatisfaction, but dont you find that your stope drills are constantly needing something new?

DRILLING CAPACITY:—As long as your stope drill will put in sufficient holes per shift to drill up your stope there is no argument in favor of your changing to our drill just because it will drill faster. We know that. But we know that the "CLEVELAND" Stope Drill will do as much work per shift when it is one year old as it will when one week old, and that is what you want, isn't it?

THE "CLEVELAND" Whether you purchase your stope drills after considering efficiency, repair cost, or drilling capacity, the "Cleveland" should be the stope drill you specify, for its design is such that the initial efficiency is the highest possible in an air tool, and the piston and valve action are so related that the "Cleveland" is just as efficient when it is a year old as when it is brand new; we **know**, and our information is gained from hundreds of installations that the "CLEVELAND" will cost less for repairs **per year** than any stope drill made; a 30 day trial will convince you that the "CLEVELAND" will drill as much per shift as any other stope drill, and we have machines always in stock ready to ship for trial if you will drop us a line, As you have everything to gain and nothing to lose, why not investigate NOW?

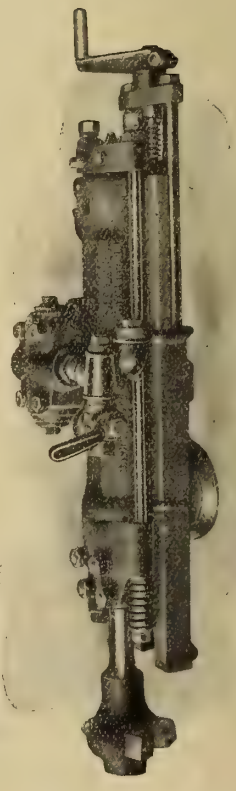
David Philip, 291½ Portage Ave., Winnipeg

CHOOSE THE RIGHT DRILL
FOR YOUR PARTICULAR CONDITIONS.



If too small, your drill holes will not be large enough or deep enough to shoot the rock economically; or your repairs will be unduly high.

If too large, labor and power will be excessive. Some valve-motions work well on heavy pressure, against hard even rock, others excel in soft or broken ground, on lower air pressure.

There is a Sullivan Drill which may be relied on to develop the highest possible efficiency and economy under any given set of working conditions.

As specialists in fitting drills to the service required, we solicit your inquiries.

Amatite ROOFING

NEEDS NO PAINTING

MOST ready roofings require special painting and coating, and unless this is done regularly, you are sure to have leaks and trouble right along.

If you use Amatite, nothing of the sort is required. You will have real roof protection *without painting* of any kind.

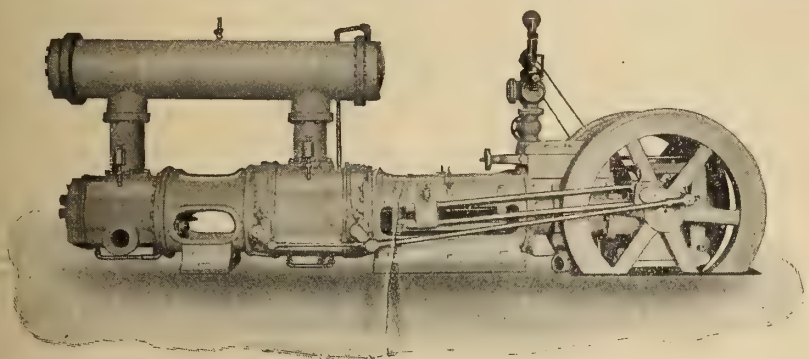
Amatite is made to stay waterproof and give protection year after year, without any thought or care on your part.

First—Because it is waterproofed with Coal Tar Pitch.

Second—Because it has a real Mineral Surface.

Amatite, owing to these features, is the most economical roofing made. Its first cost is low, and you are *saved* all future expense for repairs or paint because it will need neither.

If you haven't seen Amatite, write for a sample to-day. From it you will very quickly understand why it doesn't require painting; why it does not leak; and why it saves you money.



Address nearest office to-day.

The Davis Handbook of the Cobalt Silver District

Illustrated with Photographs

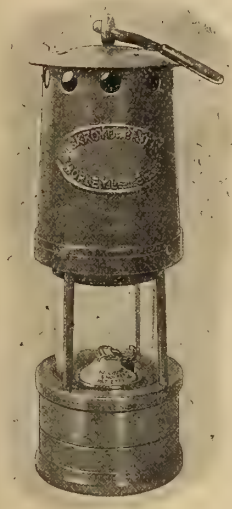
PRICE

Paper Cover = = $1.50

Stiff " = = = $2.00

by H. P. Davis

¶ The first section of this volume is an outline on the Geology, Mining Treatment and Marketing of the Ores of the Cobalt District, the object being to give all the data and general information necessary to guide investors, brokers and professional men generally.



¶ Included in this volume is a complete and accurate directory of all mining companies operating or organized to operate in the Cobalt Silver District of Ontario.

¶ Full information as to capitalization, directorates, locations and conditions of properties is given. Tabulated statements of production and dividends revised up to January, 1910, are included.

ACKROYD & BEST, LTD.

MORLEY, LEEDS, ENGLAND.

CANADIAN AGENTS:

Messrs. G. M. GRAHAM & CO.

NORTH SYDNEY, C.B.

We specialize in all kinds of Miners Safety Lamps and Electric, Magnetic and Mechanical Apparatus for same.

We have over 200,000. Lamps in use in Great Britain.

Dominion Coal Co., have 6,600.

We supply complete cabin outfits, all of the Safest and Best Quality.

Battersea Assay Goods

Battersea goods, clay and plumbago, have won for themselves a world wide reputation. They are manufactured for melting gold, silver, copper, iron, etc., etc., and are stocked by us in Montreal, ready for *immediate* shipment in an endless variety of shapes and sizes, crucibles, scorifiers, muffles, etc.

We carry a FULL LINE of THESE GOODS.

SOLE AGENTS

CYANIDE HANDBOOK BY J. E. Clennell

Over 500 pages, 6x9, illustrated, $5.00 (21s) net, postpaid

Mr. Clennell has been in close touch with the rapid developments of cyaniding. He has been instrumental, too, in many important discoveries, and his work in this field has taken him to the leading plants of the world. It deals generally with Cyanide and does not confine itself to the process alone. It is divided into nine main parts covering the subject more fully and exactly than it has heretofore been handled.

Especially noteworthy is the full treatment of recent developments and important phases heretofore *inadequately treated.*

THE ROYAL COMMISSION OF INQUIRY ON TECHNICAL EDUCATION.

Mining men have a just cause for complaint in the fact that the mining industry has been quite overlooked by the Dominion government in the recently-appointed Royal Commission on Technical Education. Of the five gentlemen appointed to the Commission, none is qualified to represent mining interests. This is a most regrettable oversight. The situation is rendered worse by the fact that some time ago the Minister of Labour was notified of the omission.

The mining industry is of such importance to Canada that a large department at Ottawa is kept up for the special purpose of promoting the development of Canadian mines. Five of our universities supply instruction in mining engineering. Very many young Canadians are devoting themselves to the study of this profession. In short, mining and its allied industries are every day becoming more and more essential factors in our national development. Where then can excuse be found for the deliberate failure of the Minister of Labour to see that the Commission included a representative mining man?

More than all other industries, mining requires special representation. Its conditions and its requirements are unique. In no other industry is specialized training so important. The lay mind is quite incapable of appreciating these facts. True insight into the meaning of the industry can only come through years of experience. No matter how admirably equipped the members of the Commission may be, they assuredly are not capable of sitting in judgment upon matters pertaining to technical mining education.

We believe that it is the duty of all Canadian mining men to protest against the manner in which the Royal Commission on Technical Education has been appointed. We believe also that the powers that be will hardly care to ignore such a protest.

THE TRANSVAAL STOPE DRILL CONTEST.

The stope drill contest, conducted under the joint auspices of the Transvaal Chamber of Mines and the Transvaal Government, has resulted in victory for two machines—the Holman and the Siskol. The first prize of £4000, was divided between the manufacturers of these two machines. The Chersen came second, winning a prize of £1000. Including these and other prizes the total cost of the contest was £17,500.

Of the nineteen original entries, only four survived the lengthy trial. The conditions were particularly severe. No changes were permitted to be made during the progress of the competition. The machines were tested

exhaustively over a period of eleven months. Whilst undoubtedly the failure of some of the drills must have been fortuitous, the success of the winners is altogether creditable.

The history of the contest we shall not touch upon. It is appropriate, however, to mention one or two of the lessons that are to be adduced. The first and most important conclusion is that the hammer drill cannot replace the reciprocating drill on the Rand. This conclusion must not be misunderstood. The Rand stopes are distinctive. They are characteristically regular. Usually they are wide. It pays, therefore, to employ a drill that has the advantage of strength and weight. Moreover, labour conditions on the Rand may have much to do with the conclusions reached. Coloured miners, supervised by Englishmen, do all the work. Thus it is probably the case that hammer drills, the efficient use of which demands more than ordinary intelligence, do not win proper recognition. All over Canada and the United States the hammer drill is proving its usefulness. It will be wise, therefore, to take South African experience with a grain of salt.

Another point particularly emphasized by the experience gained in the drill contest is that each drill works most efficiently at a certain definite air pressure. Some of the competing machines did their best work at a pressure of about sixty pounds. Others did not perform economically until higher pressure had been supplied.

The results of the contest may be summed up as indicating in general that the machine drills at present in use are susceptible of improvement only in incidentals.

A WISE APPOINTMENT.

It is a matter of much satisfaction to the mining fraternity that the Ontario Government has selected Mr. R. W. Leonard to succeed the late Dr. Goldwin Smith as one of the governors of the University of Toronto. The dignified participation by mining men in public affairs was never more necessary than at present. Mr. Leonard will prove a distinctly strong and capable member of the Board of Governors. As the only mining man on the Board, his position will be unique.

We have time and again adverted to the fact that the mining industry needs more representation on all our governing bodies. Whilst this is eminently true of our universities, it is even more true of our legislatures. Mining communities cannot hope to receive adequate assistance from governments, from railways, or from other public corporations, until such time as the mining industry has been recognized as an integral and vital part of our industrial life.

First and foremost the industry requires parliamentary representation. This is so obvious a fact that it is hardly necessary to dwell long upon it. Only thus can unwise legislation be choked, just tariffs be arranged, and numerous petty grievances be adjusted.

In the second place the profession of mining engineering and the industry of mining must be paid more attention by our educational authorities. Not one of our primary schoolbooks touches upon any phase of the industry. Our children grow up in ignorance of this supremely-important branch of professional and industrial activity.

In the third place our railways habitually ignore the claims of mining districts. Only through constant fighting can fair freight rates be secured. As a rule freight schedules, as applied to products of the mine, are arbitrarily fixed at the highest possible point. No rational basis has been developed. This is a vitally urgent problem. Upon its proper solution rests the whole future of mining in Canada.

In another editorial we have expressed our regret that mining received no consideration in the organization of the Royal Commission on Technical Education. The Dominion Government should lead in this respect. It has remained for the Ontario Government to set an example. We feel confident that the University will have every reason to congratulate itself upon the addition of a representative mining man to its Board of Governors.

CONCERNING OURSELVES.

Possibly because we are constitutionally modest we have been accused of erring in the direction of reticence concerning ourselves. Thus we hope that our readers will forgive one short excursion into the realm of self-congratulation.

Not very long ago the travelling representatives of a large Canadian manufacturing concern foregathered at their annual love feast. In comparing notes as to the merits of various media, there was found to be a singular unanimity of opinion regarding the CANADIAN MINING JOURNAL. One traveller went so far as to assert that the company's sales of mining machinery were in large part directly traceable to its advertisement in our pages. This sounds too pleasant to be true. Yet we accept it with surprisingly few qualms. In any case, it is delightful to meet this particular brand of candour. Too often the manufacturer and the sales agent prefer death to any admission of this kind.

Let us conclude this brief confession of faith with an invitation to all our advertisers to give us all the encouragement that they feel we deserve.

EDITORIAL NOTES.

Twenty-six tons of ore, sixteen tons of which was high grade, was shipped from the Wyandoh mine, on the Gillies Limit, near Cobalt. The ore was sent to the Coniagas smelter at Thorold.

Gold ore assaying $2.46 per ton is being milled at Cripple Creek at a profit of $1 per ton.

The market outlook for zinc is distinctly favourable. Supplies on hand have diminished until there is now not more than enough for forty days' consumption.

The Nevada Consolidated Copper Company, during the month of May, produced copper at a net cost of 5.91 cents per pound. This is probably the lowest figure being attained anywhere.

The purchase of a large coal mine in West Virginia by the Lake Superior Corporation is a piece of excellent commercial strategy. Coal of first quality can be landed at the Soo at a price substantially lower than was heretofore possible.

During the year ending March 31st, 1910, the Dominion Government paid $340,542 in bounties upon lead ore. The quantity of ore upon which this amount was 45,467,545 pounds. The corresponding figures for the previous year were respectively $307,432 and 42,533,287 pounds.

The Los Angeles Stock Exchange has adopted unusually stringent listing requirements. Henceforward no mining shares will be quoted upon its floors until the new regulations are complied with. In addition to a sworn statement of assets and liabilities, an engineer's report, certified and sworn to, is demanded.

The fire loss throughout Canada during the month of June is estimated at nearly seven million dollars. The use of mineral products instead of wood could easily have prevented this loss entirely. Canada loses at least thirty millions every year through fires in towns and cities. Surely it is time to prevent this calamitous waste.

Our leading editorial refers to the lack of mining representation of the recently-appointed Commission on Technical Education. A number of our readers have urged us to suggest the name of Mr. F. H. Sexton, Director of Technical Education for Nova Scotia. No name could be more suitable. Not only is Mr. Sexton admirably qualified to advise on the subject generally, but he also possesses special knowledge of mining. We doubt, however, if Nova Scotia can be persuaded to spare him.

Reports from London, England, indicate that passenger agents are attempting to profit by circulating exaggerated stories concerning gold finds in British Columbia. The tale of gold "reef," 25 miles long, near Stewart, is a fabrication. The region about Stewart is promising enough; but no good can come of such fairy tales. Incidentally, in the Portland Canal country the green prospector can not thrive. Only those who know something of hardship and of travelling over broken country can expect to "sit in."

A timely letter from Mr. F. C. Loring appears on another page. Mr. Loring touches upon the loss of time experienced in the mines of Cobalt because of insufficient ventilation. This is a subject that is too frequently overlooked by managers of metalliferous mines. As Mr. Loring points out, this neglect is attributable to the fact that the losses in efficiency are not noted . Their effect upon the balance-sheet is beyond question.

INDUSTRIAL SECTION.

While wire cloth has the advantage over perforated metal for sieving purposes, in many cases the rough or uneven surface of the former has been a great disadvantage. This has been overcome by passing the cloth between heavy rolls to flatten the crowns of the wire. The B. Greening Wire Company, Limited, has always done more or less of this work, and lately, finding the demand for same very largely increased, installed rolls to take care of the demand for medium weight screens. This proved such a success that the firm was encouraged to put in heavier rolls. These rolls are now installed, and are without doubt the heaviest rolls to be found in any wire cloth plant on the continent.

The installation of these rolls marks the completion of a wire-weaving plant that is equal to that of any concern in the world making the same class of work.

The main shaft of the Temiskaming Mine, Cobalt, will soon be the deepest in the district. It is now down more than 460 feet, and is being rapidly sunk to the 500-foot level. At this level the sixth station will be cut. At each hundred feet there is a level. There is also one at 350 feet. Below 425 feet there is no ore in the shaft itself. From the 500-foot station cross-cuts will be driven to explore for all the main veins.

Flourspar, as mined near Jamestown, Colorado, contains 70 to 85 per cent. calcium fluoride. Veins less than 1 foot thick can hardly be worked profitably. Few veins exceed 6 feet in thickness. The principal handicap to the industry is the absence of railways. Wagon hauls of 13 miles are not uncommon.

At the Ragged Chutes plant of the Cobalt Hydraulic Company, the "blow-off" rises to an enormous height when power is shut off from the mines. It is estimated that the fountain is fully 350 feet in height. It attains its maximum on Sundays when all the mines are idle.

Rumours of the discovery of large bodies of zinc-blende in the Thunder Bay district, Ontario, are current.

In Stewart, B.C., lumber costs $33 per thousand. Carpenters are paid as high as $6.50 to $7.00 per day. There is an enormous amount of building going on.

New Zealand intends to restrict the influence of the Standard Oil Company. Anti-trust legislation is being framed with this object in view.

THE MECHANICAL CHARGING OF BLAST FURNACES.

BY EDGAR J. W. RICHARDS AND THOMAS LEWIS, GLENGARNOCK.

(Abstract of paper read before the Cleveland Institution of Engineers, Middlesbrough, England.)

In our manufactures we have always been a conservative nation, and there has been a tendency to let other countries try experiments and develop new ideas, although there never has been a lack of inventive genius in this country. As in other things, so it has been in the matter of the mechanical filling of our blast furnaces, for although various classes of machines have been introduced, and their benefits proved almost in every other industry, yet at the blast furnace, which is in reality the prime factor in all our manufactures, we for the most part adhere to our old-fashioned methods.

We will show you later a photograph of a mechanically-filled furnace in operation at Lowmoor Iron Works, as far back as 1800, and we understand many years ago, the late Mr. Snelus had a mechanically-charged furnace at the West Cumberland works. It

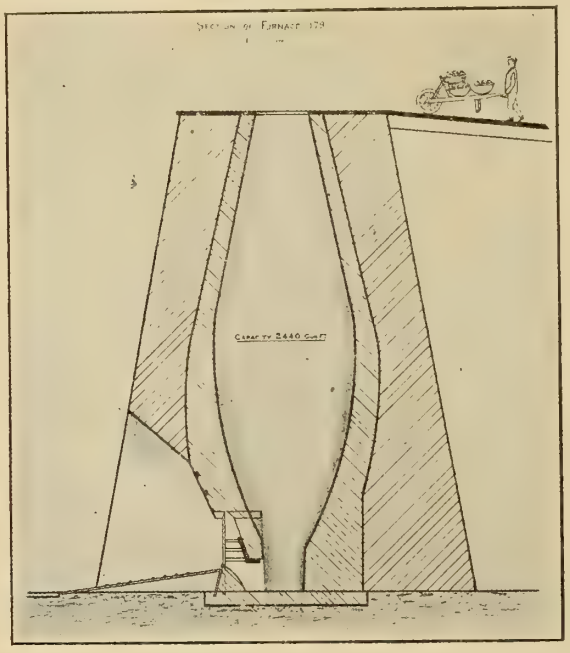

Fig. 1

is, however, in America and Germany that most attention has been devoted to the subject.

In America, mechanical methods were forced upon them, owing to the opening out of the famous Mesabi ore fields, the ore from which, being easily reduced, necessitated the charging to be conducted at such a high rate of speed as to be beyond the power of physical endurance. The engineer was called to the assistance of the furnace manager to supply a means of keeping the furnace full.

The full extent of the besetting difficulties of the subject were not at first realized, and it was thought to be merely a question of elevating and emptying on to the bell the required charge at the proper rate. They soon found they were labouring under a delusion; furnaces burnt down at one side owing to irregular distribution (the tipping of the skip shooting out the lumps across the hopper and dropping the fine on the near side), hot spots developed, linings were burnt out, casts were irregular in quality, slips occurred more frequently, and the furnace manager had a worrying time generally.

With such defects recognized, steps were taken to overcome them, the result being that we have now diverse methods to give a better distribution, such as deflecting plates, double bells, revolving hoppers, etc., but in spite of all this, many furnace managers still look askance at mechanical chargers, and consider that in the majority of cases, the benefits to be derived are more than counterbalanced by objections peculiar to mechanical charging, which are not found where hand filling is in vogue.

The last sentence seems to throw some light on the road to be followed if mechanical charging is to be a success. It is believed that almost no one will question the assertion that careful filling with barrows, conscientiously carried out by experienced labourers, is the most successful way to charge, and if such a

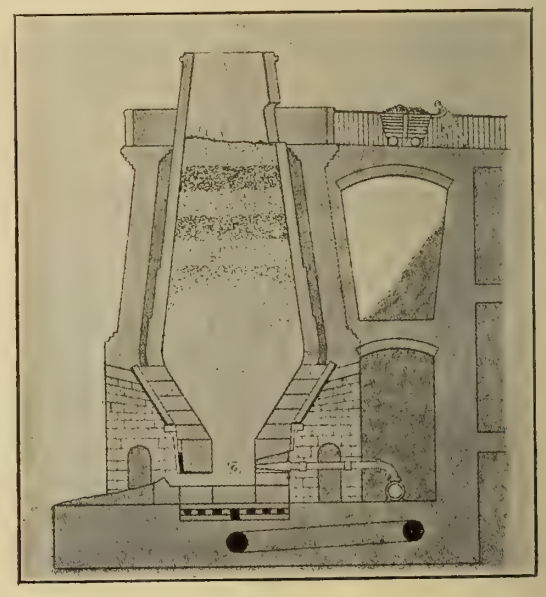

Fig. 2

charger, having the latter functions, could be got to work mechanically in an efficient manner, the initial objection would be removed.

Others contend that for large outputs exceeding say 1400 to 1500 tons per week from one furnace, mechanical methods may pay, if they are not indeed absolutely essential, but for makes up to this tonnage, there is no necessity for any other means than manual labour. We do not agree with such a contention.

Wherever there is the human element, there is the liability to err, and therefore, there is no assurance that the distribution is going to be perfect, however carefully the fillers are instructed.

Even for comparatively small makes, we are convinced that a machine can be found that will answer all requirements, work with precision and exactitude, handle the materials carefully, be under perfect control, be of course untiring, work with a steady regularity unattainable by manual labour, and generally be as

indispensable to the economical and regular working of the blast furnace as is the hot blast stove.

There is another point worth consideration. Any furnace is liable to work down quicker one day than another, and there is a difficulty in getting the fillers to keep the stock line up to the level, whereas, with me-

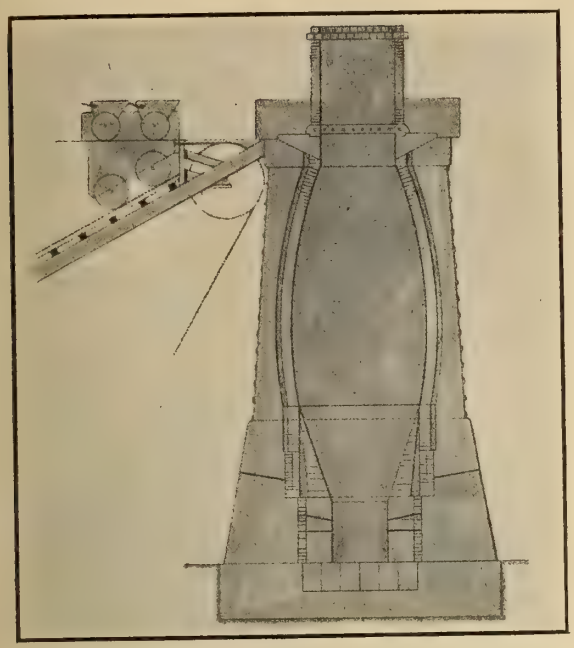

Fig. 3

chanical filling, the rate of charging can always be regulated to suit the requirements. Moreover, a much greater regularity of working of the furnace can be obtained when the funace is kept at one constant level; a difficult condition to fulfil with hand labour, but one which should always be possible with mechanical charging.

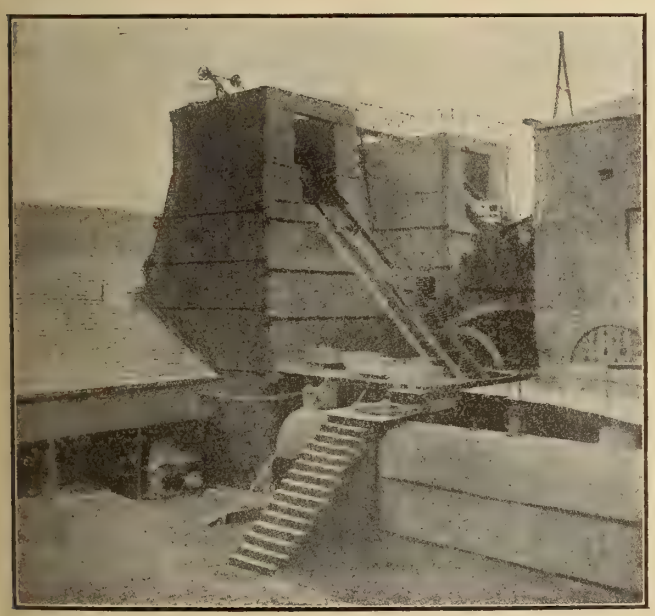

Fig. 4

It must also be remembered that everything that conduces to regularity of working of the furnace brings us nearer to that ideal state of perfection, which is the aim of every metallurgist, viz:—that, given the composition of the charge, the results of the cast can be foretold with as much exactitude as can be obtained in an experiment by the chemist in the laboratory.

Mr. Uehling has stated that in his opinion 90 per cent. of all blast furnace troubles are due to faulty charging apparatus, and he has been supported in this statement by many other authorities. The object of this paper is therefore to examine and discuss the points to be studied in the design of a suitable mechanical charger, and the faults which experience has shewn are to be avoided.

Fig. 5

We propose to summarize the chief points to be considered, to examine some of these points in detail, and then to show by diagrams typical of different designs, what has been done, and is being done, with regard to the question of mechanical charging.

The points of supreme importance which occur to us are:—

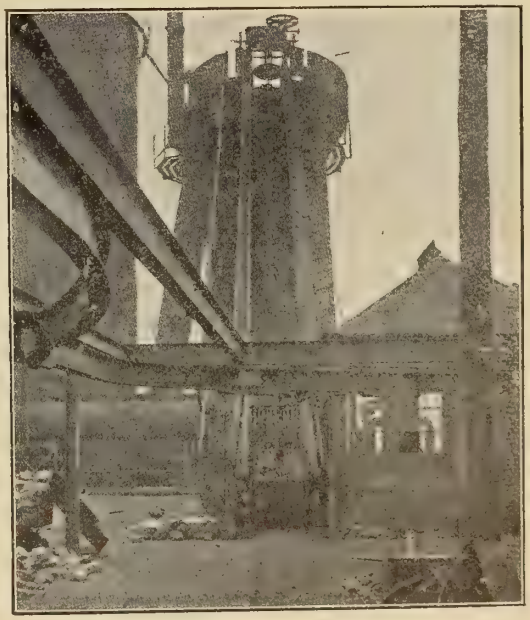

Fig. 6

1. That the material should be put into the furnace with as little breakage as possible.
2. That the material should be distributed evenly all over the surface of the stock.
3. That there should be as little machinery as possible on the furnace top.

4. That there should be no escape of gas during charging.

5. That all the movements of raising and discharging the material, the lowering of the bell, and the means of distributing the charge should be capable of being controlled from one point.

6. That the first cost and upkeep charges should be as low as possible.

7. That the design should admit of some flexibility in details to suit local conditions, and the different methods of charging.

Having summarized these points, let us refer for a little time to what is involved in the statements, and why we should consider them as essential.

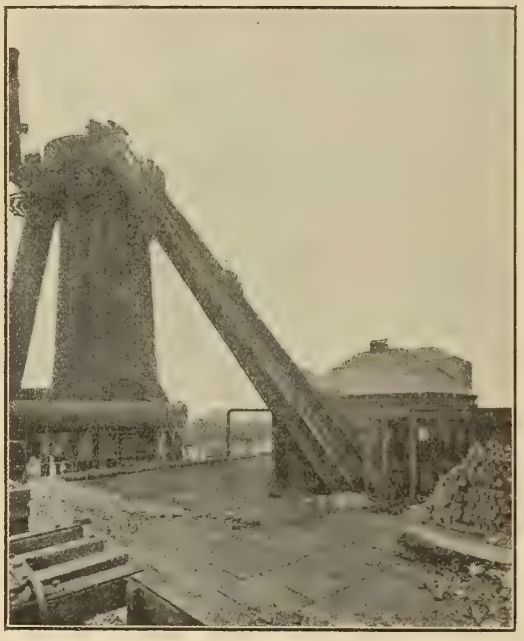

Fig. 7

Breakage of Materials.

One of the strongest objections to many of the systems of mechanical charging is the dumping and consequent breakage of the materials, particularly of the coke, and undoubtedly this is a very serious consideration, and one which has hitherto prevented many furnace managers from adopting mechanical means.

Some of the arguments in this respect appear, however, to be based on fallacious premises, and might equally well be applied to hand as to machine filling. Certainly there are chargers that do knock about the materials much more than is necessary, and we will again refer to this point when some typical designs have been illustrated, but in many cases this argument does not apply.

It is a common thing to find a furnace manager object to a charger because of the drop of from 5 feet to 10 feet on to the bell, but does it never occur to him that if the stock line were visible to his sight, the drop on to the bell would appear insignificant compared with the drop from the bell into the furnace?

On the other hand many mechanical devices err, not so much in the height of any one drop, but in the number of such drops, the material being thrown this way and that way several times in its passage from the stock ground to the furnace, with the idea of getting the materials well mixed, but greatly to the detriment of the more friable portions of the charge, and for this reason the double bell tpyes with connecting sleeve have fallen under a great deal of condemnation.

The ideal charger, then, must be one that eliminates as far as possible the breakage of materials by reducing the drop to a minimum, and especially by avoiding the multiplication of the number of such drops.

Distribution.

Furnace managers may have various opinions with regard to the method of charging, and as to whether the materials should be mixed or charged in layers—local conditions may require special consideration on these points—but on one point all are agreed, that the materials must be evenly distributed over the furnace.

This principle is recognized in charging with barrows into the ordinary cup and bell, where the charge is distributed evenly all round the hopper, so as to give an even distribution of fine and lump, and a good mixture of the materials of the charge.

Fig. 8

Several attempts have been made to get a better arrangement for distributing than Parry's cup and bell, but hitherto none has been very successful, and they require too much attention to be of much service in mechanical charging.

Although several of these devices are very ingenious, yet by studying the conditions in each individual case, the class of material, and the diameter of the furnace at the stock line, the authors are convinced that a size of bell can be got for any furnace, which can give quite satisfactory results so far as radial distribution is concerned, provided that other parts of the furnace are proportionate, and certainly nothing simpler than the cup and cone can be devised.

It is when we come to the circumferential distribution around the furnace that we have to give the matter more careful consideration, for with the high pressure and speed of working of the modern furnace, a very slight difference in the density of the materials at one point may cause an infinite amount of trouble. For example, a bell that swings slightly off the centre for a short period has been found to be sufficient to destroy the lining at one side, by leaving a freer passage one way than another. Might not this be taken as an argument for balancing a bell as carefully as one would balance a flywheel? Another case is on record of a furnace where the charge was deposited on four points of the bell continuously, and it was found that the

furnace lining burnt out to a rectangular shape, the four angles of the rectangle corresponding with the points midway between the points of dumping, where the percentage of lump was highest. Instances might be multiplied but the examples given above are sufficient to indicate the importance of the question of correct distribution. However carefully the charge is deposited, it may yet happen that the stock line becomes uneven, and it may be found necessary to fill up one part of the furnace, or, to use the furnaceman's phrase to "put in blanks." We must, then, in designing a charger, have such a method of control that we can do this, otherwise we are going to discount the advantage gained at the furnace top by introducing trouble in the furnace itself.

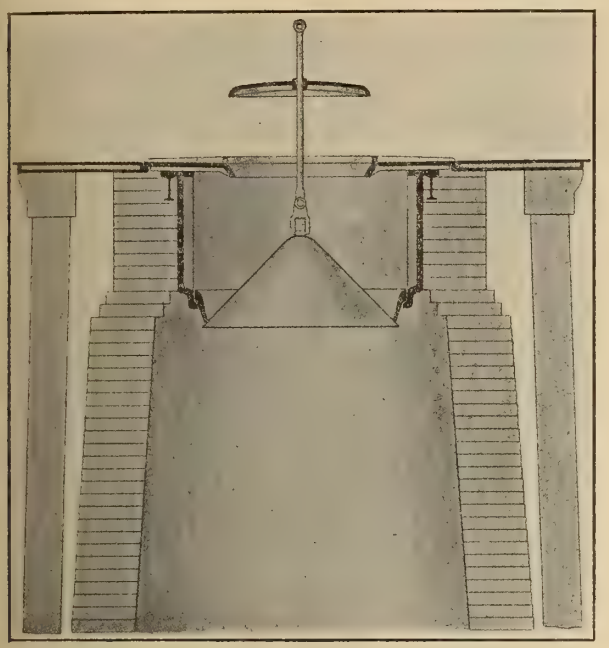

Fig. 9

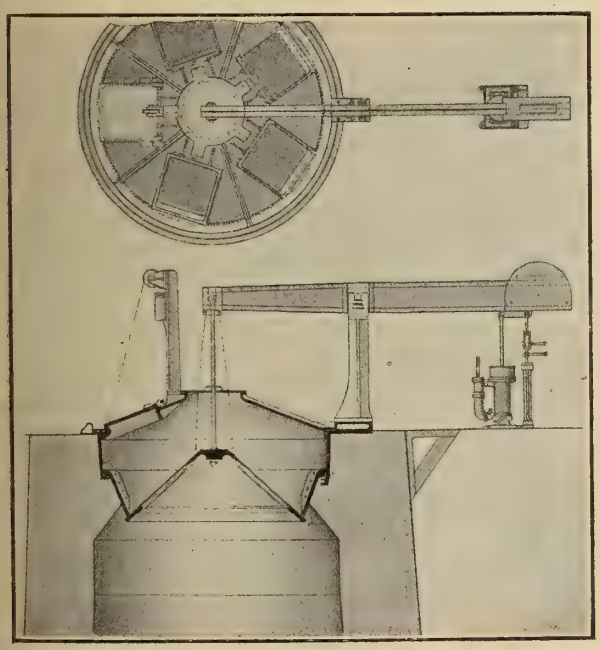

Fig. 10

As before mentioned, it is almost universally admitted that no better distribution can be got than by the system of filling by hand barrows, if it is carefully and conscientiously carried out, and the aim in mechanical charging should be to adopt methods as nearly as possible approximating to the conditions of hand charging.

Gearing on Furnace Top.

Under conditions such as prevail on a furnace top, exposed to the inclemencies of the weather, and to heat, dust and gas, the upkeep of elaborate gearing is a costly item of expenditure. To make a serviceable charger, some gearing is necessary in order to distribute the charge, but this should be reduced to a minimum, and be as much as possible protected from the deteriorating influence mentioned above. In several designs there is a great complication of gear wheels and shafting carried right over the furnace in the most exposed position, and it is a matter of no surprise that furnace managers condemn them. Unfortunately the sins of a few are visited on others to whom these strictures do not apply.

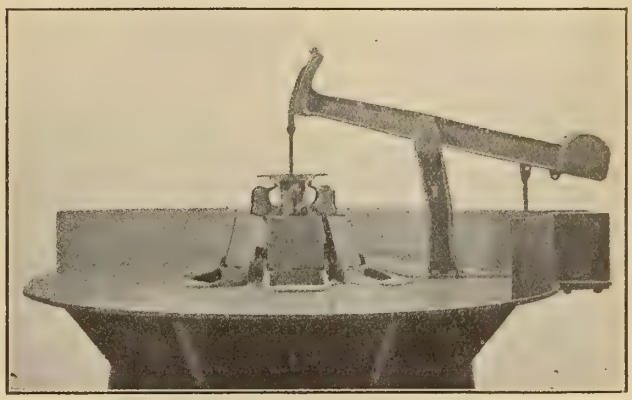

Fig. 11

Escape of Gas.

Now let us devote a little time to the question of the escape of gas from the furnace top during the lowering of the bell, if no means is used for preventing this.

Putting aside other considerations for a minute, look at what the loss of gas alone means in times when every cubic foot is either a valuable asset, or of considerable value in the works, whether for heating stoves, firing boilers, or driving gas engines.

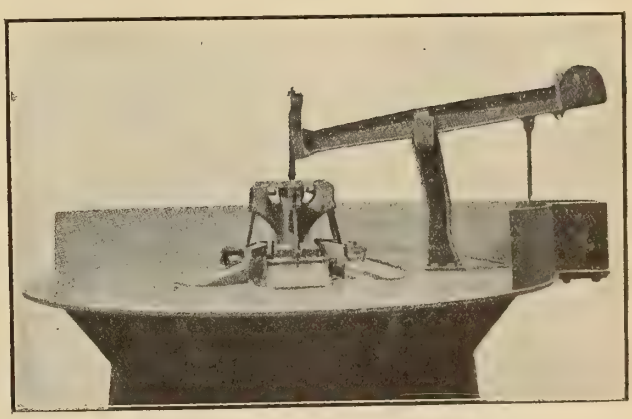

Fig. 12

Take the case of a furnace with an output of say 200 tons per day, or say with a burden of mine and fuel with fluxes of 800 tons per day, and let it be assumed that each hopper-full lowered into the furnace represents 15 tons, then in the course of a day the bell is

lowered 53 times, and gas is lost on each day's work to the amount of about 20 to 25 minutes' production. For larger outputs the loss would, of course, be proportionately greater. Besides the actual loss, we have to consider the effect on the works plant. This is so well known to you as to need no description.

It may be said that mechanical charging is not the only way to eliminate this evil, and the authors readily admit it. Several devices have been used to prevent the escape of gas, even with barrow charging; one of the authors of this paper patented such an arrangement some years ago, and a similar arrangement is in use on all the furnaces at one of the works of our firm.

One point of advantage in a closed top soon becomes evident when a bell sticks for any reason, as it prevents the far from beautiful pillar of fire and smoke which is too frequent a feature of our landscape.

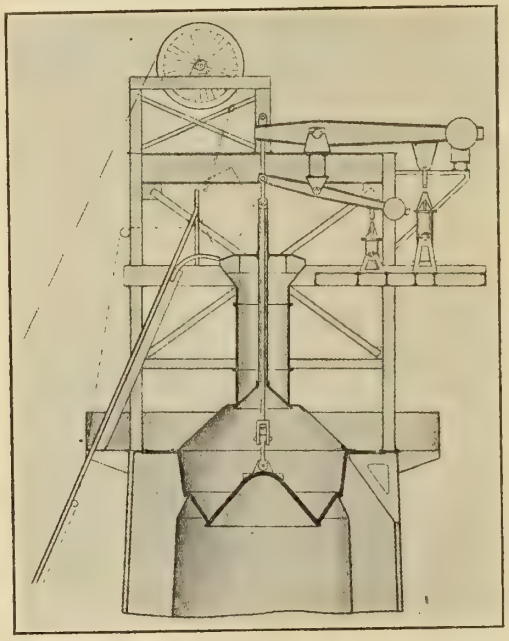

Fig. 13

The prevention of gas escape, which, even in barrow charging is advisable, to say the least of it, becomes absolutely imperative in many mechanical chargers where there is a head gear over the top of the hopper.

Control from One Point.

That the control of all the mechanism, raising and lowering of the bell, distribution, etc., should be concentrated at one point is so apparent as to need no arguments to support the statement, and the perfection attained by instrument makers in the manufacture of recorders and indicators, makes it a simple matter to arrange for a central control.

Capital and Upkeep Cost.

That the first outlay, and the cost of upkeep should be a minimum is also self-evident, and the charger which can combine efficiency with low cost is the one of the most commercial benefit. With the complicated gearing in use on some chargers, the gain effected to the manufacturing department is outbalanced by the extra labour devolving upon the engineering staff to keep the plant running.

Flexibility of Design.

As different ores may require different methods of charging, or managers may have their own ideas as to how the materials should be put into the furnace, it is advisable that a charger should be capable of being modified in details to suit local conditions. Thus, at one place it may be required to take a skip with about say a 6-tons burden, and at another place a smaller skip may meet the requirements, or it may be preferred to send up the ordinary barrow to be automatically

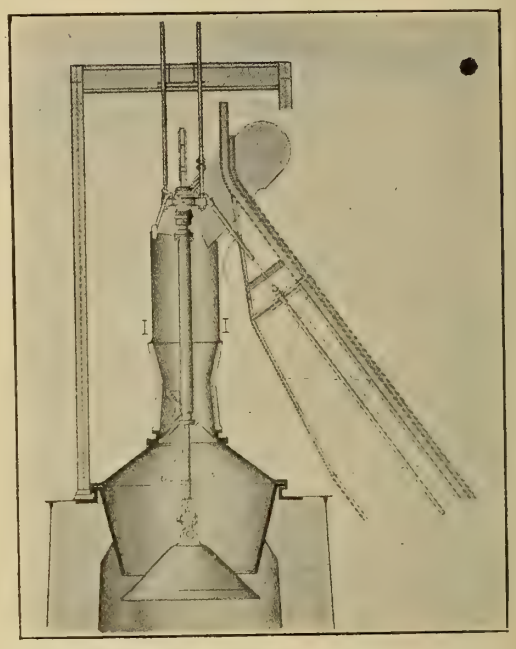

Fig. 14

discharged. Where so many works have their own coke ovens, it would also be an advantage to send the coke oven skip to the top without further handling.

It is preferable, therefore, that a charger should be capable of embracing these several requirements, and

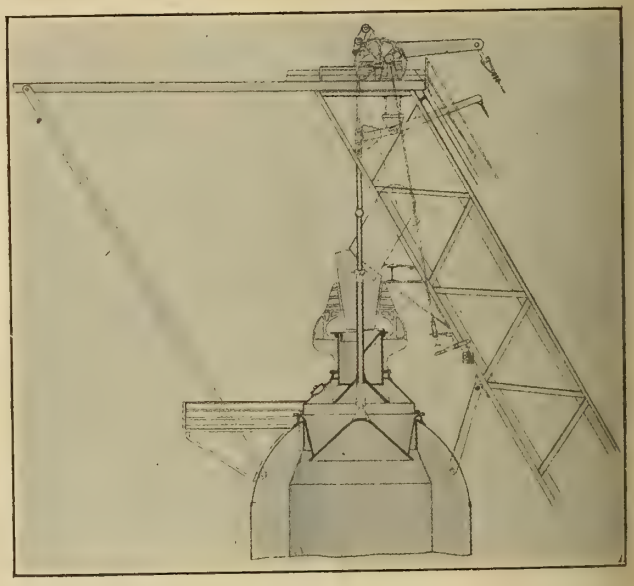

Fig. 15

not be designed to suit one particular form of charging only.

Having discussed the chief points of interest and importance in mechanical charging, we will now look at some illustrations of different methods of filling furnaces, mechanical and otherwise, which will show the progress that has been made in this direction.

By the kindness and courtesy of Mr. Woodcock, we are enabled to show (Fig. 1) a copy of an old drawing of one of the original Lowmoor furnaces, built in 1791, and the method of charging by baskets, in a manner similar to that in use at many cupolas at the present day.

We see here an old type of furnace filled by a four-wheeled bogie (Fig. 2). It will be noticed that the filling is effected from one side, a method in vogue in Staffordshire in the early seventies.

This system was altered by the late Sir Lowthian Bell to charging from four points, which effected a radical improvement both in economy and output, and is referred to by him in his papers on blast furnaces, published in the "Iron and Steel Institute Journal" of 1872.

Note also the bank behind the furnace, which was an essential feature of all blast furnaces at one time. As furnaces were raised in height, or built in localities where there was not a convenient hill, it became neces-

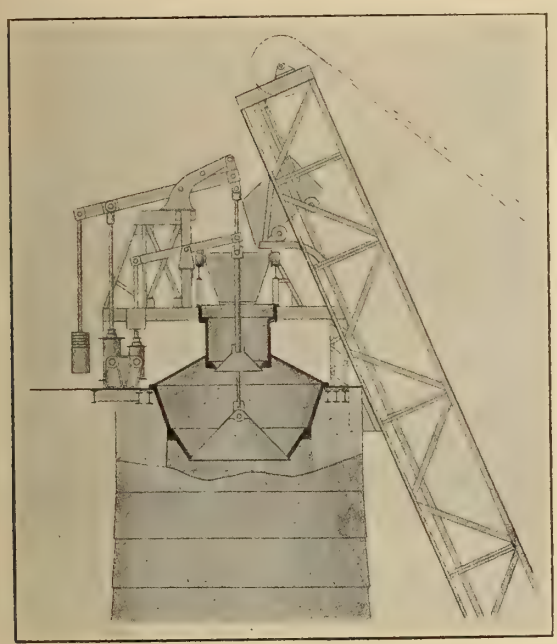

Fig. 16

sary to use some description of hoist, and here (Fig. 3) we see one type of hoist, viz.:—an inclined plane with a level staging on which the barrows were placed.

We show this type in place of the usual vertical hoist because in mechanical charging an incline is always used, and it is interesting to note the points of resemblance between this and the next view, (Fig. 4), viz.: the mechanically charged furnace at Lowmoor already referred to, and for the reproduction of which here we are also indebted to Mr. Woodcock.

This arrangement was adopted in 1800 in place of the basket filling, already described, and the method of working was as follows: The four-wheeled trucks seen in the photograph were filled with the charge and brought on to the lower staging, from which they were run on to the travelling carriage on the incline. This carriage has a frame running on four wheels on the track, and an inner swinging frame pivoted on the sides of the carriage, this inner frame receiving the truck which was secured in position. On running the carriage up the incline, two pulleys on the front of the swinging frame engaged with two projections on the rail, thus tipping the contents of the truck into the furnace.

Although not in chronological order, it is interesting for the purpose of comparison to see the next four views, (Figs. 5-8) which show a charger at present in use at the blast furnaces of the Langloan Iron & Chemi-

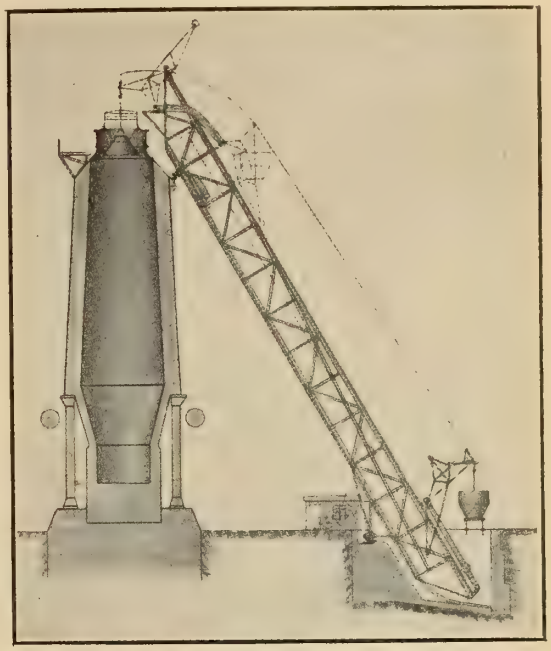

Fig. 17

cal Company, Limited, Coatbridge, this being the only mechanical charger in use in Scotland. The authors have to express their appreciation of the kindness of Mr. A. Moore, manager of Langloan, in permitting them to show you these slides.

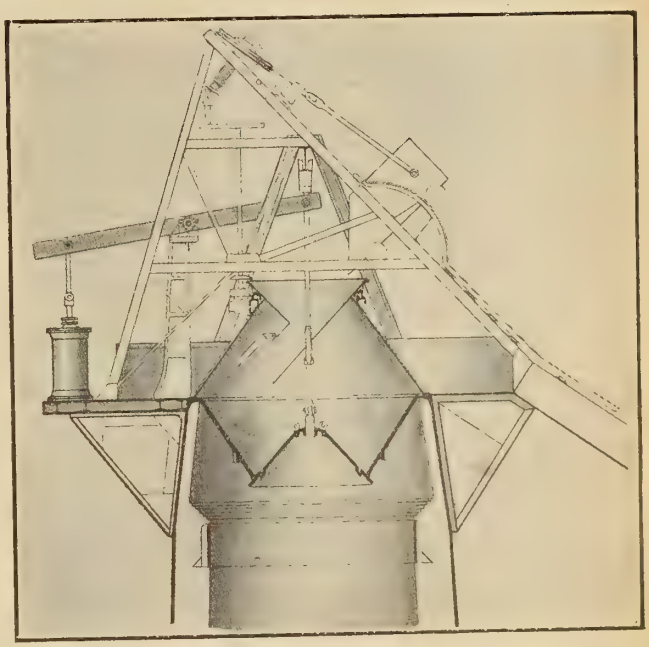

Fig. 18

The next two views show different methods of preventing the escape of gas in hand-filled furnaces at the Clyde Iron Works of Messrs. James Dunlop & Company, Limited (Fig. 9), and at the Ardeer Iron Works of the Glengarnock Iron & Steel Company, Limited, Ayrshire (Fig. 10). We have to acknowledge the kind-

ness of Mr. Rogerson and Mr. Main respectively in supplying us with the drawings.

The top shown in the next two, is one patented by the reader, and already referred to. (Figs. 11 and 12.)

To come now to what we might call the present era of mechanical charging, let us examine a few types, and try to find out the object in view in their design, and whether they fulfil the conditions we have formulated.

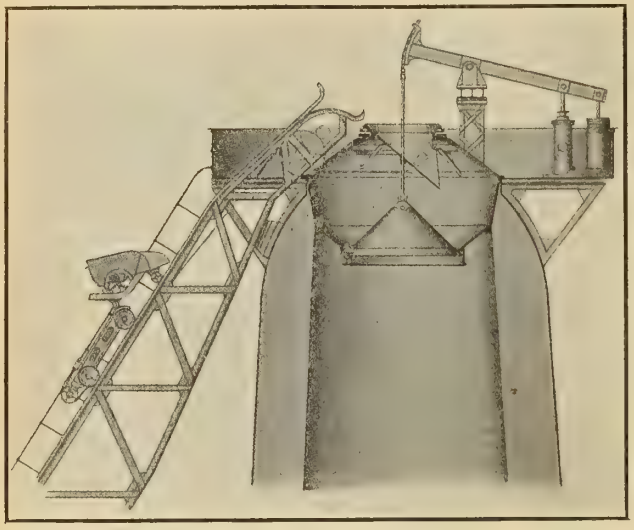

Fig. 19

The next illustration (Fig. 13), shows an early type as made in America, before the difficulties of the subject were realized.

It will be noticed there is no revolving mechanism—the charge is dumped into the long sleeve-like top hopper, discharged from that into the main bell, and thence into the furnace.

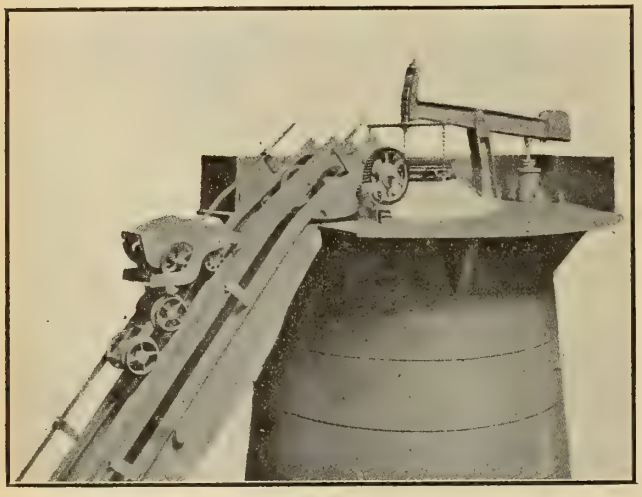

Fig. 20

The long sleeve was adopted in this type to concentrate the charge as much as possible on the centre of the main bell, with the idea of giving each part of the hopper its correct share of the charge. It was found, however, that this was not sufficient to mix the material, and it also caused considerable breakage of the coke. The fine and lump, separated owing to the action of the skip in discharging, kept their relative positions, more or less, in moving down the sleeve, and were discharged on to the main bell with the finer material collected, for the greater part, on the side next to the skip, and the coarser on the opposite side.

The natural result was that the furnace lining burnt out on the side where the coarser material was thrown, and as the blast was concentrated chiefly at that side, the life of the furnace was very much shorter than if there had been an even distribution, not to speak of the increased liability of slips and scaffolds.

It was after this was noticed that deflecting plates were introduced, and here is seen (Fig. 14) a typical charger with deflector and revolving hopper. This certainly is an improvement, so far as distribution goes, but in the majority of this type the long sleeve is retained, and the drop of the material before reaching the furnace is excessive. The top gear, too, is cumbersome, and makes the bell difficult of access for repairs, and also the mechanism for revolving the top, is, in most cases, too delicate for a blast furnace, and causes a great deal of worry and loss of time in upkeep.

That this type of charger still has its advocates is indicated by the adoption of it on the new plant of the United States Steel Corporation at Gary, though from the illustration here shown of it (Fig. 15) it seems to

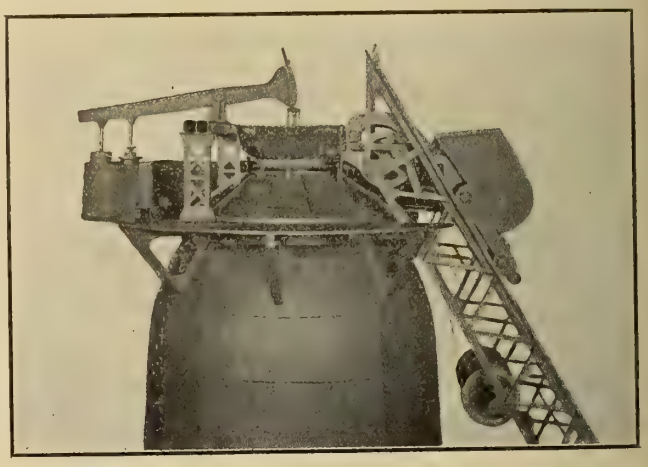

Fig. 21

us it would hardly recommend itself to managers in the Middlesbrough district, owing to the heavy top gear, and the levers and mechanism on the furnace top.

Another type of distributor for use with a double bell, and one which is known to the Middlesbrough district is here shown (Fig. 16). In place of revolving the top hopper, this is made in two pieces which can be drawn back, or inclined at various angles to effect a distribution according to the class of materials used. The idea is well worked out, but the objection seems to be that the material gets too much knocked about, and the distribution is not sufficiently positive.

This illustration (Fig. 17) may be taken as a type of charger greatly favoured in Germany, the method of raising and depositing the hopper varying somewhat in different designs, but it is typical of the general method employed. Here a hopper fitted with a bell on the under side is conveyed from the stock ground to the furnace top, and placed on a casing over the main bell and hopper, the material being thence transferred to the main bell by lowering the conical bottom.

This removes the distribution trouble from the furnace top to the ground, and does away with the necessity of gearing at the top of the furnace to revolve the hopper. There is still the difficulty of how to fill the hopper on the ground level. At some places the hopper is filled from bins placed on opposite sides of a

central railway along which the hopper travels, but we have already pointed out the effect of dumping at four points of the bell, and its bad effect on the furnace, and this would be aggravated in the case of filling from two points. Of course the hopper may be revolved during filling, but the arrangement is apt to be cumbersome, and in very few cases could it be applied to an existing plant.

The next type which you see reproduced here (Fig. 18) will be recognized by many of you as that made by The Brown Hoisting Company, and shows a distinct improvement on those preceding it. This is almost universally acknowledged to be the best system of charging hitherto in vogue, and the reason of it seems to be, that it is the nearest approach to barrow charging that is in use at the present time. There are still, however, in our opinion, one or two defects, such as the high top gear, and the mechanism above the hopper (though these details have been modified somewhat in later designs by this firm), we should also think that difficulty

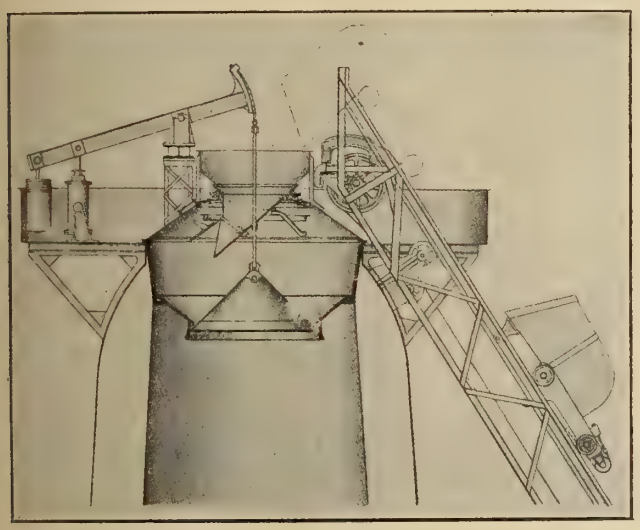

Fig. 22

might be experienced with the levers inside the furnace top for closing the door, and while it approaches very nearly to the method of barrow charging, it does not quite get there.

The next illustration (Fig. 19) is the charger which the authors have been experimenting with, and in the design of which are embodied all the points which we have enumerated as being essential to a satisfactory charging machine.

On first sight the charger seems to bear a certain facial resemblance to that last shewn, but on closer examination it will be seen that certain improvements have been introduced, which have effected a radical change in its efficiency. Let us study the charger more closely to see what these improvements are.

The revolving of the chute is actuated by an intermittent motion, the chute moving forward after every second skip is discharged, and the mode of operation is as follows:

There is provided a double track, so that one skip may take up ore and limestone, and the other one the fuel. The ore skip first ascends and deposits its charge on a point of the bell in accordance with the position of the revolving chute at that moment. The skip of coke is then discharged at the same point and over the ore, precisely as is done in hand filling. Before the next charge reaches the top, the chute has revolved through part of a revolution, so that the ore is placed slightly round the bell, and its lot of fuel placed on the top of it, and so on, until the round is completed, but notice that the gearing is so arranged that on the completion of the round the chute has travelled slightly more than a full revolution, and that therefore the dumping points are continually moving on round the bell in a gradual precession.

This disposes satisfactorily of the question of circumferential distribution, and as already stated, the question of correct radial distribution is one merely of the correct proportion between the size of the bell and the throat of the furnace, modified by the class of material in most constant use. This proportion is one that cannot very well be fixed by any formula, but is best arrived at by experiments on a model, the sizes of materials being proportioned to the scale of the model.

Another important feature of this design is the facility which it affords for the placing of "blanks" at any circumferential point of discharge into the hopper. The

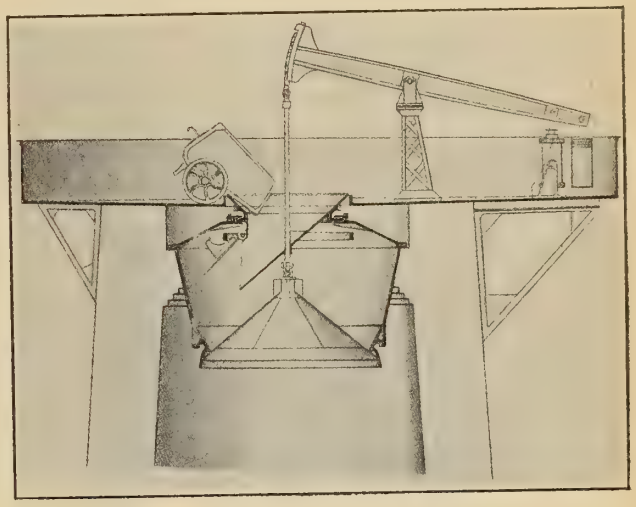

Fig. 23

intermittent motion of the chute already referred to is transmitted from the hoisting mechanism to the chute through a clutch (Fig. 20), therefore by throwing the clutch out of gear, as many skip loads as desired may be deposited at one point in the hopper.

To eliminate as far as possible the breakage of materials, the height of the charger is brought down to the minimum, and the changes of direction of the materials in passing from the skip to the bell are made as easy as possible. The charger can be used with an ordinary furnace barrow, avoiding the dumping into a skip, or the coke oven skip may be used, and thus one fruitful source of breakage in mechanical charging may be adopted as indicated in this slide (Fig. 21), where the movement of the chute is continuous instead of intermittent.

Let us now consider the question of gas escape. It has come to our notice that though means have been devised for this purpose, they have not always been successful, and we have therefore aimed at attaining a method at once simple and effective.

The means adopted by us consists of a ring encircling the chute, which, when lowered, engages with an arm on the door, and thereby closes it. The ring may be operated simultaneously with the lowering of the bell by attaching it to the bell lever as here shown (Fig. 22), or by means of a separate cylinder actuated by fluid pressure, an electric or otherwise driven winch,

or any other mechanical means. The use of the ring commends itself on account of its simplicity and positive action, irrespective of the position of the chute.

When the ring is worked by independent means the door may be closed before commencing to lower the bell. If, however, it is hung from the main bell lever, the bell travels a short distance before the door is closed. To minimize the escape of gas during this period, there is added to the lower edge of the hopper an extension or sleeve, which fits as closely as practicable to the bell. This retains the greater part of the charge on the bell till such time as the door of the chute is closed, and thus practically eliminates the escape of gas.

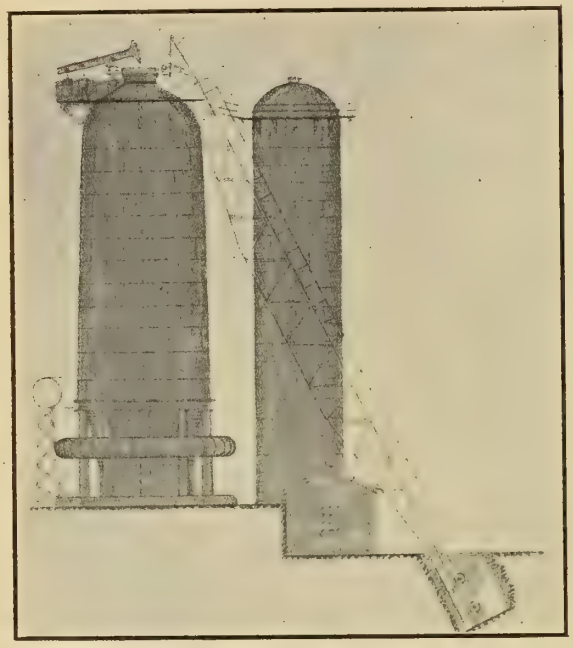

Fig. 24

If it should happen that a firm cannot see its way to make the outlay for an individual hoist for each furnace, but still wish to prevent gas escapes from the top while lowering, then the same type of top may be used without the hoist and automatic tip. This involves, of course, the use of barrows, but it is only necessary to wheel the barrow to the point nearest to the hoist, and the distribution may be effected by a crank handle worked by hand, or by mechanical means, the arrangement of the top for this purpose being shewn on the slide now before you. (Fig. 23.)

The simplicity of the whole design, the low height, the small amount of gearing, and this kept below the hopper lever, the consequently comparative low first cost and upkeep charges, do not require any words to commend them, as a look at the general view now shown, (Fig. 24), makes them apparent to the sight, and this can be confirmed by a study of the model.

We have now laid before you our views on the subject of mechanical charging, and we have endeavoured to make an impartial review of the chargers in use hitherto, none of which completely fulfils the conditions we have formulated, and we have placed before you a design of a charger, which, while we do not say it is the last word on the subject, appears to us to come closer than any other to that ideal charger which every furnace manager wants, that will keep his furnace working with steady regularity, cheaply and efficiently, and by putting a limit upon the vagaries of the blast furnace, will reduce the worries of that sometimes much harassed man, the furnace manager.

SOUTHERN PART OF LUNENBURG COUNTY, NOVA SCOTIA.

By E. R. Faribault.

(From Summary Report of the Geological Survey.)

Introduction.

During the past season, the writer was occupied in completing the geological and topographical mapping of the southern part of Lunenburg County, along the Atlantic Coast southwesterly from Mahone Bay to Volger Cove, and extending inland to Bridgewater. This completes the surveys and other field work necessary to finish the Malone Bay sheet, No. 88, and the Lunenburg, No. 89.

The assistants in the field were Messrs. J. McG. Cruickshank and M. Y. Williams.

For the purpose, particularly, of indicating the lines which prospecting should follow in the district, as well as to facilitate the work of operating mines, attention was given, in an especial degree, to the structural geology; since it has been established that the gold-bearing veins occur, almost exclusively, along anticlinal folds. The development in the rocks of a strong, slaty cleavage, obscuring the bedding planes, and the widespread drift cover, concealing the surface, made the accurate location of the various anticlines and synclines both difficult and tedious.

Character of District.

The district surveyed is for the most part covered by low, undulating hills of glacial drift, seldom over 300 or 400 feet high, having a general north and south trend and forming prominent headlands along the sea coast. The intervals between the hills are generally occupied by swampy land and chains of small lakes; or by rocky barrens affording good rock exposures; or they are strewn with granite boulders and debris from the north.

Lahave River crosses the area in a southeasterly direction, and occupies a marked depression; which is continued as an inlet of the sea, less than a mile wide, for 12 miles to Bridgewater; affording good navigation for large and small vessels. Petite Riviére, a stream of less importance, runs into the sea six miles farther west, and has several waterfalls along its course that are partly utilized for small mills.

Lunenburg and Bridgewater, the two chief towns of Lunenburg County, are situated in the area examined. Lunenburg, the most important fishing station in the province, has an excellent harbour, and has a large trade with the West Indies. Bridgewater is a progressing railway and lumbering centre at the head of navigation on Lahave River. Settlements of fishermen are scattered along the sea-shore of the mainland and islands; especially on many small, rocky coves and inlets which afford good shelter for boats.

In the vicinity of the coast there is little land suitable for agriculture. Small farms and gardens are successfully cultivated by the use of an abundant supply of fish refuse and seaweeds as fertilizers. Inland, between Bridgewater and Mahone Bay, there are good farms and several fine orchards.

Geology.

With the exception of a few small patches of lower carboniferous limestone and gypsum on Second Peninsula, and some of the adjoining islands, the whole area is occupied by the series. No rock exposure could be found on Second Peninsula, because of a heavy covering of glacial drift; but numerous angular blocks of shell limestone and grey compact limestone were observed at several places along the north shore, from the Government wharf to Bluff head, also on the north and south side of Mason Island lying between the two peninsulas. These deposits indicate the position of the outer edge of the lower carboniferous basin of Mahone Bay and St. Margaret Bay referred to in the Summary Report for 1907, page 79.

Several specimens of invertebrate fossils, obtained in 1907 and 1908 from various localities in the Mahone Bay basin, were examined by Mr. Lambe, who reports that they consist of one species of coral and two species of brachiopods; all characteristic of the lower carboniferous limestone. The respective species, together with the localities from which they were obtained, and Mr. Lawrence M. Lambe's descriptions, are as follows:

(1) Lithostrotion Cœspitosum, Martin.—Specimens from Sheep Island, Goat Island, and the south end of Stephen Island, in Mahone Bay. These specimens are of interest, as the species has not hitherto been recorded from this side of the Atlantic. L. cœspitosum was originally described from the carboniferous limestone of England.

(2) Dielasma Sacculus, Martin.—Half a dozen specimens, from Mahone Bay, belong to this species, which was primarily described under the name of Terebratula sacculus, also from the lower carboniferous of England, and was later recorded as occurring in rocks of the same general horizon by Sir J. William Dawson (see Acadian Geology) at a number of localities in Nova Scotia.

(3) Productus Cora, D'Orbigny.—Specimens of a large Productus from Goat Island, Sheep Island, south end of Stephen Island, Seaboyer's on the south side of Deep Cove, and north shore of Second Peninsula. The species represented appears to be an unusually large form of P. Cora, d'Orbigny, which is found abundantly, but of smaller size, in the carboniferous limestone of Nova Scotia, and is widely distributed in the carboniferous of Europe as well as America.

Gold-bearing Series.

Practically the whole of the district examined, with the exception of the small areas of lower carboniferous limestone and gypsum on Second Peninsula, is underlain by the quartzites and slates of the gold-bearing series. In the absence of fossils or other conclusive evidence, this great series of rocks has been referred to the lower Cambrian, though, possibly, it may be Pre-Cambrian.

The whole series falls naturally into two distinct lithological divisions: a lower one, called the Goldenville quartzite; and an upper one, called the Halifax slate.

The Goldenville division is mostly composed of thick-bedded, bluish and greenish grey quartzite, locally called "whin," interstratified with numerous beds of slates of different varieties and colours, and from a fraction of a foot to several feet in thickness. This division constitutes the productive gold-bearing rocks of the province.

The Halifax division is made up of argillaceous slates, generally of a dark grey colour, in many places graphitic and pyritous, and varying to greenish-grey or light grey in colour. Some beds are quite arenaceous with occasional thin layers of flinty, quartzose rock, generally heavily charged with iron pyrites.

The rocks of the Goldbearing series in the region examined have been forced into a succession of parallel folds, running northeasterly and southwesterly.

The greatest width of the area of the Goldbearing series in the district examined, measured at right angles to the folding, is 16 miles. A transverse section along a line from Bridgewater to West Ironbound Island gives eight major anticlines and seven synclines, with a few minor folds. The courses of the axes of folding were all located and traced across the area surveyed.

The following list of anticlines and synclines, gives the order in which they occur along Lahave River from West Ironbound Island to Bridgewater, together with the gold mines situated along the anticlines:

Moser Island anticline.
1. Spectacle Island syncline.
Dublin Shore anticline. The Ovens gold mines.
2. South Parks Cove syncline.
Park Creek anticline.
3. North Parks Cove syncline.
Pentz Section anticline. Indian Path mine and Somerset gold discovery.
4. Middle Lahave syncline.
Wentzel Lake anticline.
5. Pleasantville syncline.
Juniper Brook anticline.
6. Upper Lahave syncline.
Conquerall Bank anticline. Dares Lake gold discovery .
7. Dayspring syncline.
Bridgewater anticline. Leipsigate and Blockhouse gold mines.

As already stated, the greater part of the area is occupied by the Halifax slate division. The Goldenville quartzite is brought up to the surface only in the southwestern part of the Lunenburg sheet, where the Dublin shore anticline and the Pentz Section anticline have a pronounced pitch to the eastward, forming two prominent, broad domes of quartzite extending southwesterly beyond the limits of the area examined.

The southern dome of quartzite begins on the seashore half a mile east of West Dublin post-office, spreads out in a broad circle and extends southwesterly on both limbs of the Dublin Shore anticline, including Green Bay with the inner part of Cape Lahave Island on the south, and the mouth of Petite Riviére and the head of Broad Cove on the north.

The northern dome of quartzite begins 3 miles to the northwest of the southern one, on the eastern side of Petite Riviére, 1 mile east of Crouse Town post-office, where it circles around Brown Lake on the eastern pitch of the Pentz Section anticline; the south limb extends southwesterly toward Volger Cove, and the north limb westerly toward County Line station on the Halifax & Southwestern Railway.

On these two domes the interstratified slates, at certain horizons, are in much greater volume than the quartzites, especially near the top of the division, where they attain a great thickness. The line of demarcation between the two divisions is thus not nearly so well de-

fined in this district as it is in the eastern part of the province, the passage from quartzites to slates being more gradual.

Igneous Rocks.

The only igneous rocks observed were four dioritic dikes on the Ovens Peninsula. The dikes are well exposed on both the east and west side of the peninsula, at a distance of a quarter of a mile south of the Ovens gold mine, and immediately south of the old mill of the Acadia Gold Reduction Company, still standing on the eastern shore of the point. All four occur within a distance of 250 feet; they vary in width from 3 to 9 feet, and are generally conformable in strike and dip with the stratification of the slates, though in many cases, they distinctly cut across them. The only other instance of a basic eruptive occurring in the Goldbearing rocks along the coast is at Tangier, where a dike cuts across the sediments at right angles to their strike. In the Gaspereau Valley and its vicinity many similar dikes have also been observed intruding both the Goldbearing series and the Silurian.

Glaciation.

The entire area must have been covered with moving ice at the time of the glacial period. The general course of the ice, as indicated by striæ, was toward the south and southeast, conforming to the directions of the valleys of Lahave, Petite Riviére, and other main streams, and to the general trend of the hills. Glacial drift, largely made up of till, with granitic boulders, and of debris transported from South Mountain, covers most of the hills. Debris of amygdaloidal traps and other characteristic basic eruptives from North Mountain on the Bay of Fundy coast, was also observed at many places, showing that at some period, at least, the ice field moved across the whole province.

Economic Geology.

Gold.

The slates of the Halifax division of the Goldbearing rocks are generally considered by the miners to be much less likely to bear auriferous veins than the quartzites and slates of the Goldenville division, because, so far, no important mine has been located on them anywhere within the province; except at Caribou. Rich veins have been found in them, but these were generally small and irregular, and without the uniformity and extent of those occurring in slate belts lying between rigid walls of quartzite. It may be remarked, however, that in the eastern part of the province, on account of the deep glacial erosion, the slates of the upper division seldom occur along the anticlines, and much less often on the domes which are the only favourable places for the formation of gold-bearing veins.

In the region under study, every one of the eight anticlines occurs in the slate of the Halifax division, and only two of them have brought the quartzites to the surface, namely, the Dublin Shore and the Pentz Section, where these rocks occur at the southwestern end of the anticline. The Dublin Shore anticline passes through the "Ovens" gold district, and the Pentz Section anticline passes through the Indian Path gold district and the Somerset gold discovery. Special detailed surveys have been made of the gold mining districts of the Ovens and Indian Path, but a report on the structure of these districts must be deferred until all the surveys are plotted and compiled.

Somerset Gold Discovery.—On May 20th, 1905, rich "float" gold quartz was discovered by Nathaniel Slaughenwhite of Italy Cross, at Somerset, on the west side of Petite Riviére, one mile south of A. Slaughenwhite's house, at the south end of Beach hill. The quartz is dark, ribboned, and striated, indicating that it came from an interbedded vein having a thickness of about 10 inches. During the following two summers a surface pit was sunk 63 feet north of the first discovery through 26 feet of drift to the bed-rock, and a tunnel was driven north for 57 feet, on the bed-rock. No float of the rich ribboned quartz was found in this exploratory work. This may have been due to the fact that the discovery is situated on the eastern pitch of a broad anticlinal dome of quartzite and slate, where the veins, conforming to the stratification, have a general north and south directon. East-west, or at right angles to the probable direction of the vein, should, therefore, be the more promising direction for exploratory tunnelling .

The same rule should be applied in prospecting at the Augustus Reinhardt discovery of rich gold float, similarly situated on the same anticlinal dome, about one mile west of the Slaughenwhite discovery.

Iron Ore.

Some of the dark, rusty-weathering slates of the Halifax division are heavily charged with iron pyrites, generally occurring in small cubes distributed through the rock, or in massive form along the bedding planes. From the decomposition of these slates have originated deposits of bog iron ore found in various low, swampy places, along rivers, and about lakes. Several such deposits were observed, notably along both banks of Lahave River, and on the hill extending to the north of Kingsbury to Rose Point. It is doubtful if any of these deposits are of sufficient extent and depth to be of commercial value, but they might be worth investigating as they are nearly all situated within easy reach of good shipping points.

Limestone and Gypsum.

The presence of limestone on Second Peninsula appears to have been generally overlooked by the present inhabitants, though it was certainly known to the earlier French settlers, who had a limekiln on Limestone Hill, opposite the Government wharf, and one on Goreham point, once thickly settled by the French.

Gypsum was not observed anywhere, but several large funnel-shaped "sink-holes" were located on the Second Peninsula, on the farms of John Young, George Acker, and Freeman Berringer, testifying to the occurrence of deposits under the heavy drift covering. As these deposits of limestone and gypsum are quite close to the Government wharf, where good shipping facilities are available, they may prove of commercial value.

Clay.

Extensive deposits of alluvial clay occur at many places along the low, swampy intervales, and glacial clay, largely made up of granite debris, is abundant on many hills. Samples of some of the more promising clays were collected for examination as to their value for brick making.

A brick-yard was in operation about 65 years ago near Lunenburg, at the Saltpit wharf on the south shore of Back harbour. It is reported that bricks were also made by the early French settlers on Brick Hill, situated on Goreham point on Second Peninsula.

Archaeology.

Indian implements, including arrow-heads and spear-heads, flint, and pieces of earthenware, have been found on Backman beach on the north side of Second Peninsula, and at other places along this part of the coast. Specimens of these are on exhibition in a small museum in the town hall at Bridgewater, and in the archæological collection of the provincial museum at Halifax.

RAMBLER-CARIBOO MINE, SLOCAN, B. C.

BY E. JACOBS.

In the course of a recent trip through the Slocan district of British Columbia, I visited the Rambler-Cariboo mine, among others. As reports of discoveries of ore in that mine during the last few months have renewed interest in it, the following information relative to the property is contributed:

The Rambler-Cariboo group embraces five mineral claims, having a total area of 175 acres, situated in McGuigan Basin, Slocan mining division, West Kootenay, and distant from the Kaslo & Slocan Railway about three miles by wagon road. It is owned by a company incorporated on July 31st, 1899, as the Rambler-Cariboo Mines, Limited, with British Columbia office in Kaslo. Mr. W. E. Zwicky is general manager.

Prior to 1904 development work consisted chiefly of a shaft with levels opened from it. This shaft was sunk 500 feet from what is known as the 300-foot level, the original workings, down to 300 feet, having been adits in the mountain-side above it. Levels were opened from the shaft at each 100 feet down to what is known as the 800-foot level, below which it was found to be impracticable to work the mine with the power plant with which it was then equipped, for in the spring of each year pumping especially would have been too heavy for the available power. By that time much ore had been extracted, and from the profits earned, $230,000 had been paid to stockholders as dividends.

At the beginning of 1904 the directors found themselves in this position—they had to choose between buying and putting in a larger power plant, with its necessary increased cost of pumping and hoisting; driving a long adit to cut the vein at greater depth and thus provide for the drainage of the mine at little or no cost after the vein should have been intersected by such deep level working, and, too, keep the hoisting costs down; or abandoning the mine. Another important consideration was the altitude of the surface works—concentrating mill, mine buildings, etc. — which was about 6,000 feet above sea-level, and in a place where snow-slides were troublesome every spring.

Mr. Zwicky strongly recommended the driving of a deep-level adit. At first this proposal did not meet with favour, for it involved a large expenditure of money, and the work, while it would take a comparatively long time to carry out, would not bring in any revenue until after its completion and the mine had been opened at levels below the old workings. Eventually the directors recognized the wisdom of adopting their general manager's recommendation, and financial arrangements were made to carry out his plans. My recollection is that $75,000 had to be provided for the work, but whatever the amount, the money was found and the work proceeded with. This was the most important deep-level work that had been undertaken in the Slocan, and it was known that if success should result, other mines would be opened in a similar way.

The work of driving the adit was commenced on July 9th, 1904; it was completed on April 16th, 1906. The portal is at a level 1,450 feet below the highest point at which the vein had been opened, and 2,400 feet lower than the apex outcrop on the summit of the mountain; it is 650 feet lower than the 8th or former bottom level of the mine. At 4,523 feet from the portal, driving the adit was discontinued. Allowance having been made for running off water, the depth at the face of the adit is 1,425 feet below the highest point at which the vein had been opened. I have stood at the breast of the adit and from there seen daylight at the portal, distant nearly seven-eights of a mile. The excellence of the engineering and workmanship in driving this adit, which is 7 feet by 7 feet 6 inches in the clear, was therefore plainly evident.

Writing of conditions as he found them about the close of 1907, Mr. Robert R. Hedley, in his description for the Dominion Department of Mines' Report on the Mining and Metallurgical Industries of Canada, 1907-1908, observed: "The manager of the Rambler-Cariboo mines states that owing to some disturbance or fault at or about the point to which the vein had been projected on this level, the vein was not found, though the tunnel was driven for some 90 feet beyond. He consequently concluded to cut the vein at the nearest possible point under the main shaft. A diagonal drift was then run, and from this drift a raise made to the upper workings. In 200 feet of raise the 1,250-foot level was reached, and a cross-cut started, which, after being driven 47 feet, cut the vein. It was there 8 feet wide and showed several streaks of clean galena. Raising was continued, and some driving done at the 1,150-foot level. Stations were established at the 9 and 10 levels. Some stoping was then undertaken in the upper levels, and the work of connecting the tunnel by a suitable shaft proceeded with. The requisite equipment of the portal was installed, and suitable cottages, bunk-houses, etc., for the new camp near the mouth of the tunnel, were erected."

When in the Slocan last January I was informed that the 900, 1,000 and 1,100 levels had been opened, and ore had been found in several places down to the 10th level. The ore was silver-lead, with but little zinc. Here it may be mentioned that during the period from 1893 to 1906, inclusive, shipments of ore from the mine aggregated about 14,500 tons, having average metal contents as follows: Lead, 37 per cent.; zinc, 14 per cent.; silver, 127 ounces per ton. The output in 1909 was in excess of 1,000 tons of a somewhat lower grade than the average above stated, yet sufficiently high to pay mining costs and, as well, provide enough money for cost of the exploration included in the 1,200 to 1,300 feet of development work done in that year. Latterly production has been maintained at the rate of about 100 tons per month, and it is well known that recent discoveries of ore have been such that a larger output could be regularly made without difficulty were it considered advisable to increase production at this time, when prices of silver and lead continue comparatively low.

The ordinary annual meeting of stockholders in the Rambler-Cariboo Mines, Limited, was held in Kaslo on June 14th, but little, if any, publicity was given to the proceedings thereat. One of the directors, however, was reported to have made the following statements at Nelson to a press representative:

"The new ore shoot has been opened on three levels —the 700, 800 and 900; these have been connected by a raise in ore all the way. On the 700-foot level the ore-shoot has been opened for a length of 40 feet; it has an average width of two feet of solid galena. On the 800-foot level the ore-body is 82 feet long, and the vein varies in width up to 18 feet. The 900-foot level has been in ore for more than 90 feet; the vein ranges in width from 8 to 12 feet, and an estimate shows 18

inches of clean shipping ore. This ore shoot is entirely distinct from any other heretofore found or worked in the mine, being a long way to the south of the old workings. It contains native silver, which had not previously been found in the mine. A general average of the ore thus far developed gives a value of 65 per cent. lead and 174 ounces silver per ton. Practically all the ore is of excellent grade, but there is some concentrating ore on all three levels, especially on the 800-foot. We have still about 150 feet to drive on the 1,000-foot level to reach the ore shoot; when that shall have been done we shall raise in it to the 900-foot level. After that work shall have been accomplished, two still lower levels will be driven to find the ore shoot at greater depth. Meanwhile stopes are being opened above the 900-foot level, and then production will be increased. The last round of drill-holes on the 900-foot level fired while we were at the mine broke down nearly a carload of ore.

"Lessees are now working the company's concentrating mill on the dumps from the old workings, and from this source there will be shipments of concentrates made, in addition to the ore from the lower levels. We are now employing 35 men at the mine."

To the foregoing it may be added that before any considerable increase in output shall be regularly made more development work will be done, so that later a proportionately larger tonnage can be produced. It is characteristic of Mr. Zwicky that he keeps his development work well ahead of his ore-stoping, which policy has proved a prudent one.

There is no doubt the Rambler-Cariboo is now in better condition to return substantial profits above ordinary operating costs than at any other time for years. The successful outcome of the enterprise planned six years ago by Mr. Zwicky, whose wise foresight was not at that time generally recognized, is of much moment to the Slocan district as a whole; indeed, this has been proved by the subsequent action of other mine-owners, for at least two other deep-level developments have been carried out, one with success and the second with good prospects of also justifying the enterprise with which it has been undertaken. Recognition of the pluck of the directors of the Rambler-Cariboo Company, themselves large stockholders, in financing what at first seemed a somewhat hazardous as well as costly undertaking, is also merited. They had full confidence though in their manager's skill and good judgment, and the sequel has proved that it was well grounded.

DIAMOND DRILLING IN NOVA SCOTIA.

Written for THE CANADIAN MINING JOURNAL.

The government of Nova Scotia has for some years encouraged diamond-drill prospecting by keeping a number of drills in commission for bona-fide prospectors. Last year, or, rather, during the twelve months ending September 30th, 1909, eight drills were operated.

Four of these were diamond steam drills, three were Calyx steam drills, and the remaining two were hand drills, diamond and Calyx respectively. The core dimensions ranged 15/16-inch to 7 inches, the latter being the diameter of the core drilled by a Calyx steam drill. The range in depth is from 400 feet up to 3000 feet.

In the twelve months mentioned above, the total number of holes put down was 14, their combined depth being 5,577 feet. More than half of this footage was done by diamond drills, which have 3,378 feet to their credit, leaving 2,198 feet put down by Calyx drills.

No. 8 drill, a light steam diamond drill with a capacity of 1,500 feet, was purchased and operated during the year. It has the latest type of hydraulic feed, and produces a two-inch core.

The total expenditure during the year for maintenance of drills, store-house, repairs, wages, etc., including the purchase of No. 8 drill, was only $6,012.55. Since the year 1899, when the government purchased the first drill, the total expenditure has amounted to $71,385.47.

No holes were lost during the year. The average cost per foot for all boring was $1.405. The average cost per foot for boring by diamond drills was $0.79; by Calyx drills, $2.166. The carbon-cost per foot for boring by diamond drills was $0.037; while the shot-cost for Calyx drills was $0.055.

The following comparison of costs is useful:

	1908.	1909.
Cost per foot for all boring	$1.06	$1.405
Cost per foot for all boring by diamond drills	0.845	0.79
Cost per foot for all boring by Calyx drills	1.34	2.166
Shot-cost per foot for all boring by Calyx drills	0.056	0.055
Carbon-cost per foot for all boring by diamond drills	0.077	0.037

Drill No. 1 was employed from September 28th, 1908, to November 17th, 1908, putting down a hole for the Nova Scotia Steel & Coal Company, near New Glasgow. No. 1 is a 6-inch core, steam Calyx. The mineral sought was coal. The total depth of the hole was 361 feet 3 inches. Shales and sandstones, the former often very hard, alternated irregularly. Fireclay was encountered at 177 feet. The total cost of this hole was $647.54, or $1.80 per foot, made up as follows:

Labour	$277.18
Management	170.82
Fuel	147.50
Light ,oil, waste, etc.	5.13
Shot	6.75
Lumber	16.66
Casing-pit	14.00
Shot-bits	7.50
Gravel	2.00
Total	$647.54

The average rate of boring was 0.7 of one foot per hour. The fastest rate of boring was 5 feet 10 inches in one hour. Double shift was worked.

Drill No. 2, a steam diamond drill producing a 15/16-inch core, capacity 850 feet, operated from September 26th, 1908, to October 15th, 1908, in No. 1 Allan shaft of the Acadia Coal Company, Pictou County. The mineral sought was coal.

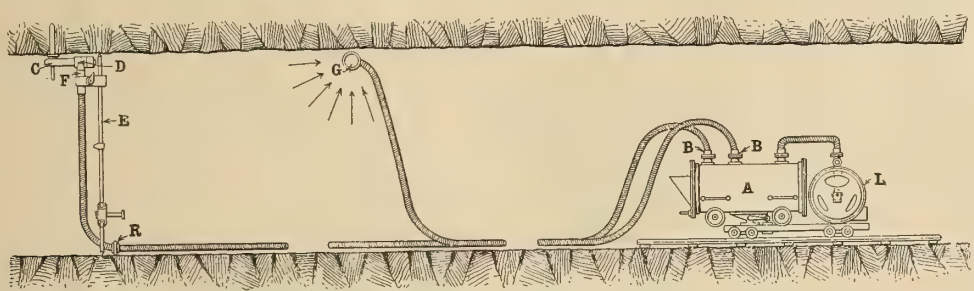
Banded gray shales and dark gray shales with bands of hard brown ironstone were encountered. A total depth of 318 feet 9 inches was reached. The hole cost $189.21 or $0.595 per foot. The average rate of boring was one foot per hour. The fastest rate of boring was 4 feet 4 inches in one hour. Another hole put down by the same drill in the same locality cost $109.70 for 191 feet, or $0.574 per foot. This hole was stopped in 14 feet of coal. In one other hole sunk by a hand diamond drill, a considerable amount of conglomerate was cut. In this instance the cost per foot went up to $1.38.

Drill No. 6, a 6-inch core steam Calyx, sunk a hole at River Inhabitants. The total depth was 851 feet 6 inches. Boring double shift, the average rate of pro-

gress was 0.4 foot per hour. The fastest rate of boring was 11 feet 5 inches in one and one-half hours. The total cost was $2,832.23, or $3.33 per foot. Coal was the mineral sought. Blue and black shales, and hard gray sandstones made up the strata drilled.

Drill No. 8, a two-inch core diamond drill, 1,500 feet capacity, sunk a hole 710 feet on the property of the Intercolonial Coal Company, Stellarton. The average rate of boring was 2 feet per hour. The fastest rate was 3 feet 8 inches in one hour. The total cost was $643.87, or $0.906 per foot.

The department supplies and maintains drills. Applicant pays all operating expenses, including freight.



WEAR ON FILTER LEAVES.

When transferring vacuum filter leaves into the wash tanks the heaviest wear is at the corners, which scrape on the sides of the tanks. As soon as the canvas is worn through the leaves become useless. To avoid this heavy canvas patches should be sewed over the corners. This will considerably prolong the life of the leaves.

ELECTRO-PNEUMATIC APPARATUS FOR REMOVAL OF DUST IN MINES.

By Frank C. Perkins.

The accompanying drawing shows the construction of an English design electric fan apparatus for the removal of dust in mines and indicates its method of operation. The use of percussion rock drills on hard stones in mining has the disadvantage that the miners in charge of the drills are obliged to inhale the fine particles of rock giving rise in some instances to a disease known as "Miners' Phthisis." The electric-driven apparatus noted in the drawing has been successfully used to overcome this difficulty and remove the dust which caused the trouble by utilizing a small cylindrical tank indicated at A, this being partially filled with water and chemical absorption agents if required.

This apparatus mounted on a truck has two or more branches, BB, to which rubber hose are coupled by means of patent rapid couplings; at the end of one hose is fixed a light aluminium sucker C, which fits around the drill hole, and is held in position by an adjustable arm, D, and stretcher bar E, which are made very light and portable, and of very easy adjustment; into the second hose is fixed an arrangement for clearing the gases produced by blasting. Into the sucker the dust and small particles of rock, as they are ejected by the action of the drill, are drawn by powerful air suction, the heavier particles being caught in a separator to trap at F, and in another at R, from which they can be conveniently removed, the dust-laden air being conveyed through the hose into the tank A. The attachment for use in clearing the fumes created by blasting, consists of a slotted pipe shown at G, which can be rapidly fitted across the drive, into which the noxious air and dust are quickly drawn and passed away to the tank, the atmosphere being thus very rapidly cleared.

It will be noted that the tank, with its motor and fan, is carried on a carriage running on rails. Partitions are fixed inside the tank, carrying on their lower ends hinged flaps pierced with holes. The dust-laden air enters the tank through the branches, BB, and by reason of the partitions is compelled to pass through the water on its way to the outlet branch, thus leaving behind it all dust and impurities. It flows through the fan and is discharged as pure air. The fan is of the small compound centrifugal type, driven by an electric motor.

The whole apparatus is compact and portable, the tank itself being provided with wheels, so that it can be lifted off the carriage by means of handles, placed on the rails, and moved to any convenient place for filling or emptying.

The Portland cement output of Canada during 1909 was 2,303,263 barrels.

According to statistics published by the Mines Branch, Ottawa, the value of gold won from the placer deposits of the Saskatchewan River (the only gold with which Alberta is officially credited) totalled $299,458 during the period 1887-1908, inclusive. During the three years 1895, 1896, and 1897, the annual outputs were respectively $50,000, $55,000, and $50,000. The output for 1908 was $1,037.

ELECTROLYTIC COPPER REFINING AND SMELTING IN AUSTRALIA.

Electrolytic copper refining and smelting plants are at work in Australia at the Great Cobar mine, and at Port Kembla in New South Wales. The latter plant is largely owned by the Mount Morgan mine. The multiple system is employed at both plants, and at Port Kembla double tanks are used, and an adaptation of the three-wire system is employed. At the Port Kembla works during 1909 some 5,850 tons of electrolytic copper, valued at £350,000, and bullion to the value of £124,000, were produced. Most of the blister copper treated came from the Mount Morgan mine. In former years the Mount Morgan's blister copper was electrolytically treated in America, but local treatment means a great saving in time and expense. It is surprising that the Mount Lyell mine does not send its blister copper to the local companies instead of continuing to send it to America. Probably a long contract stands in the way. As so much more of the red metal is produced in the United States of America than is consumed, to continue to send Australian copper there is like sending coals to Newcastle.

NOTES ON RECENT DEVELOPMENTS IN ASBESTOS MINING IN QUEBEC.

By W. J. Woolsey, Thetford Mines, Que.

(Abstract from the Journal of the Canadian Mining Institute.

It is generally conceded that the asbestos industry is now better established than ever before, and with stable conditions of trade must, in the near future, greatly increase in volume. Financiers have shown more than ordinary confidence in asbestos mining, and the various propositions offering have been accepted only too readily, especially if vouched for by competent authorities. Some have very severely deprecated, with justice in some cases, this recent great optimism prevailing in regard to asbestos. On the other hand, however, it must be recognized that asbestos is coming into much more general use. The increased demand, therefore, coupled with the adequacy and eminent suitability of most of the Quebec mineral, seems a sufficient reply to any who may be unduly pessimistic.

The present prices for the various grades of asbestos are from five to fifteen per cent. lower than in 1907 and accordingly shipments have been less than in that year. The outlook for the coming year is for increased shipments and a gradual improvement in prices.

The decision on the part of the operators in the Black Lake and Thetford districts to establish an Asbestos Bureau to keep the public advised of any new uses for asbestos, and the development of asbestos properties the world over, should afford the very greatest assistance in the industry.

Geological Features.

The geology of the asbestos area has lately received considerable attention from the Canadian Department of Mines, and an effort is being made to work out fully the important features as rapidly as possible. During the past thirty years many papers have been presented, and many theories advanced to explain the peculiarities observed in the district, having reference more especially to the questions of the true origin of the serpentines, the contrast between the growth of the chrysotile deposits throughout the world, and the origin and manner of growth of these fibres. Thus, valuable data bearing on these problems have been presented by Ells (a), Merrill (b), Low (c), Cirkel (d) and Dresser (e). The serpentines of the district are conceded to be of igneous origin, derived principally from rock of the peridotite class, though there are frequent instances where pyroxene appears to have been an important original mineral. The formation of the chrysotile veins has been discussed by Merrill (b), who states, "Cavities are due to shrinkage and the vein filling to processes of crystallization, extending from either wall inward." The subject is also well treated by Low (c), who states that "The cracks were probably formed by shrinkage of the mass. . . . The asbestos appears to the writer to have been deposited in the cracks under great pressure from superheated waters . . . . masses and dykes have been intruded into the serpentines, and these probably account for the necessary pressure and heated waters to form the asbestos there."

A good opportunity for studying the relations of some of the rocks containing and associated with the asbestos deposits may be found on the property of the Robertson Asbestos Mining Company, on Lot 16, Range IV, of the Township of Thetford. Here the surface outcrop measures 1,400 feet along the strike, northeast, by 600 feet in width, and consists of serpentine and a greenstone, probably diabase. The rocks lie between two beds of sedimentary rock, and all dip to the southeast at an angle of about 50 degrees. Both contacts are well marked, an interesting feature of the upper one being those fragments of the sedimentary found in the igneous rocks.

Another significant feature is that the serpentine is found along the lower or foot-wall side, while the diabase, which is a lighter rock, is near the hanging or upper wall.

Following out these observations, the purest serpentine should be found along the footwall. The writer has kept careful watch for change in the amount of asbestos, but has not found any noteworthy change towards either wall, in the amount of asbestos contained in the serpentine. The crystallization of serpentine to form chrysotile seems to be affected by other agencies than the quality of the serpentine alone. These might be pressure, heat or intrusion of dykes.

Mining Methods.

The use of cable ways is very general throughout the district. This method has been much criticised, but has, nevertheless, proved very efficient in removing material from the pits. To it may also be largely ascribed the fact that the cost of mining has been maintained at the low rate of between twenty and thirty-five cents per ton of rock delivered and loaded on the cars. The variance in costs referred to is dependent on the extent of crushing and separation of rock material in the pits. All the mines are very completely equipped. This equipment usually comprises an air compressing plant and cable ways, provided with steam, air or electric hoists. In general, electric power is in use. It is especially well adapted, when continuous service can be maintained, for the operation of the mills, as well as for mine plant. It has also been successfully applied in the operation of drills, although an electric drill has yet to be devised in which the drawback of abnormal wear of certain parts shall be overcome.

Underground mining, although successfully carried on by Bell's Asbestos Company for the past four years has not been adopted at other mines by reason of the increased cost. It is, meanwhile, interesting to note that the Bell's Asbestos Company is now installing a steam shovel plant. Mining by this method promises to be effective in the case of large holdings. A level bottom, of course, is desirable.

Milling Methods.

The question of efficiency of milling plant is one of paramount importance to those engaged in the production of asbestos fibre; but there is great divergence of

(a) Bulletin on Asbestos, 1903, Geological Survey of Canada.

(c) Geological Survey of Canada, 1906.

(d) Asbestos, its Occurrence, Exploitation and Uses, 1905.

(e) Journal of the C.M.I., Part of Vol. XII.

opinion in the matter of mill design. There is, nevertheless, much truth in the contention that the processes necessary for producing the best results vary considerably according to the class of rock to be handled. In the opinion of the writer, however, much benefit would accrue if the designing of mill plants were standardised, so far as practicable, by the adoption in all plants of the several methods which experience has taught constitute the best practice. Thus, there are several mills in the district which possess distinctive and desirable features; but it is quite possible that none is in itself absolutely perfect in design. For example, rolls have proved very efficient, since they preserve the qualities of the fibre excellently well; at the same time these machines have not yet been installed in such a manner as to provide a maximum production in proportion to the cost per ton. Again, the cyclone has proved invaluable, considered from the point of view of large production and low cost, but in determining the most desirable class of mill, the question of preserving the more valuable qualities of the fibre must, of course, be considered, and in the writer's opinion only low-grade materials should go to the cyclone, the superior grades having been saved before this stage of milling shall have been reached. The accompanying flow sheet illustrates a mill design, which in the judgment of the writer would afford the best results in respect of efficiency and simplicity of operation.

FLOW SHEET
SHOWING ASBESTOS TREATMENT THROUGH MILL

A new machine has been designed by Edward Torrey and installed by the Asbestos & Asbestic Company, of Danville, Que., to overcome the difficulties met with in the old style cyclone. In the new machine the reduction of the ore is effected more directly by impact than by pulverization, which is the principle of the old style cyclone, where the beaters revolve in opposite directions. It is claimed for the Torrey cyclone that the injury to the fibres occasioned by the old style cyclone is largely overcome, and that the operation of the new machine is less costly.

ADDRESS BY F. H. SEXTON, DIRECTOR OF TECHNICAL EDUCATION, NOVA SCOTIA.

At the recent sessional closing of the Nova Scotia Technical College, Halifax, N.S., an address was read by Director F. H. Sexton. Part of this appears herewith. Mr. Sexton has accomplished much for the cause of modern and sane education in Nova Scotia:

"This is the first commencement day of the Nova Scotia Technical College—an event that is bound by the mere circumstance to be important in the educational annals of Nova Scotia. For this is the People's College, established by the people, maintained by the people and for the purpose of offering special opportunities to the children of the people. Its motto is "Science for the common weal" and it is to be dedicated to the advancement of science and industry. It stands primarily for applied science and its aim is to give the people that scientific knowledge which shall give them such power over nature that by industry their leisure and well-being may be advanced. This college will grow into an inspiration and bulwark of the highest industrial life of this province if its motto and dedication are adhered to, and to-day we stand at the first milestone.

"The mere presence of the college is fraught with import to the community in which we live. It is of great value to the ten or twelve thousand homes that constitute this community to have such an institution where their boys—or girls, either (applause)—can secure an engineering training of the highest order, for a mere trifle and still be at home. It means much to have a staff of experts in engineering who may be consulted on specific questions. It is important to have in the midst of a city, a college with well equipped scientific laboratories and libraries for the purpose of experimentation and research. It is also no mean advantage to the community to have placed within it a large imposing expensive building with ample lawns. The fact that students gather from other points in the province and spend eight months of every year, besides many hard-earned dollars, is no serious menace to the city. There are other advantages that I could enumerate if I had not already far trespassed into the confines of modesty. I honestly think that the people of this community do not give the educational institutions such as Dalhousie College, St. Mary's College and Technical College, and the many other ones with which the city is blessed, half the consideration and appreciation that they deserve.

"The college will also mean much to the industrial life of the whole province. It will turn out young men thoroughly trained to eventually become our captains of industry. These men will be the ones who will conserve our natural resources and turn the wastes of manufacture into dividends. It his been stated by a competent designer of power plants, that if the installations were all built on the most approved design, a saving could be made on the production of the average plant of ¼ cent. per H. P. hour. This would mean a saving of nearly $400,000 yearly in Nova Scotia alone. Somebody has figured out the true value of a trained engineer to the community and it is a fabulous amount over and above the amount it cost to educate him. Nova

Scotia shall train Nova Scotians to manage Nova Scotia industries and we shall not have to import trained men to occupy the least servile position. The college will also carry on industrial research as applied to the special needs existing in Nova Scotia, and will eventually be of the greatest service in developing the future industries of the province.

"It is interesting for us to note that the establishment and maintenance of this institution by the provincial legislature is in harmony with the growth of the state universities of the United States. Some of the universities are bidding fair to outstrip even the most ancient and honoured of the privately endowed institutions such as Harvard and Columbia, both in number and income. Universities like Wisconsin, Michigan and Minnesota, recently received grants of between one and two million dollars for a two-year period. People are also leaving large bequests to state universities at present, a practice that was not nearly so frequent in the early history of these institutions. It is to be hoped that some large-minded patriot will realize the sphere of usefulness that this technical college is striving to occupy and will assist in some handsome way the efforts to train men for a practical useful life, either as a captain or non-commissioned officer of industry. The state university idea has spread eastward during the past year and President Schurman, of Cornell University, whom we are all proud to acknowledge and honour, has secured a change in the charter looking toward state control, and, consequently, aid by state appropriations. Thus we see that the establishment of the Technical College by and for the people is in entire accord with the most significant movements of the times in university support and control.

"Again, it is interesting to see how the Technical College in its relation to the secondary schools under its direction has reached the same solution of an educational need as the most advanced policy of the University of Wisconsin, which has led the other colleges of the United States. The fact that correspondence schools as private corporations were so successful in giving practical instruction to men in different trades pointed to a great need for such instruction. The university, in striving to be of as much educational service to the state as possible, started a whole series of correspondence courses of its own. These were based on the soundest educational principles, and were not conducted on a money-making basis, as were the private correspondence schools. The success of these courses in Wisconsin startled even the men who had charge of them. It was found necessary after a short time for the greatest success of this work to hire local or travelling teachers to explain the correspondence work. In this way local classes and schools have been formed.

"In Nova Scotia it is estimated that a sum of $60,000 or $70,000 went out of the province every year for correspondence courses. This showed the great need that existed for secondary technical instruction. This need was met by the establishment of local technical evening schools for workingmen. These have been most successful, but it has been found that all the needs cannot be filled without establishing correspondence courses under the Technical College. Equal needs are ultimately satisfied with equal measures.

"In establishing secondary technical schools under the direction of a college, the University of Wisconsin and the Technical College were leaders in America. The tendency of most universities in Canada and the United States has been too conservative. They have consulted their own interests selfishly in their requirements for entrance. They have constantly raised these, as more and more was demanded of the college graduate in order to keep the course in college the same length. The high schools and academies have strained to make the graduation requirements the same as the entrance into college. This was to the great detriment of most of the students in the academies, because only a small percentage entered college at all. Thus the college was responsible for the fact that by far the largest portion of the pupils in the higher grades of the public schools were being trained to go to college instead of being trained primarily for actual life.

"I think it was the agricultural college which set the example of greatest educational service to the people whom it was intended to serve. They were the first who went to the people to find out exactly what was needed and then to try to make every effort to supply the needs. They were the pioneers who took the education right to the door of the man who should have it. Their methods of travelling dairies, lectures from the rear ends of trains, and many more organized efforts were looked on askance by other more conservative faculties of the university. Now that the state universities have taken the cue from the agricultural colleges it is possible that we shall see the application of the principle of carrying the higher and more special kinds of training to the whole people. We shall also see the university guiding and inspiring the whole work instead of autocratically dominating it for the special ends of the University. It is right that the highest end and aim of the university should be the same as that of the leader and followers in the Christian church service."

ORE PRODUCTION IN BRITISH COLUMBIA.

The total quantity of ore produced in British Columbia in 1909 was 2,057,000 tons. This includes ore put through stamp and concentrating mills as well as that smelted. It is not practicable at this time, when returns available for the purpose are necessarily incomplete, to judge how the figures for the half year just closed compare with those of the last calendar year, and even an estimate would be little more than a guess so far as the production of mines in Ainsworth, Slocan and the Coast district are concerned. Yet it is practicable to make a fairly reliable comparison of the tonnage of ore produced by mines in two or three of the more important camps in the first half of 1909 and 1910, respectively, and since this will serve to indicate in a general way that progress has been made this year, it will be done.

Taking first the larger mines of the Boundary district, which produced about 70 per cent. of the total tonnage of ore mined in the province last year, the following approximate figures are shown:

Mines.	Tons. To June 30, 1909.	Tons. To June 30, 1910.
Granby Company's	478,000	625,000
B. C. Copper Company's.....	139,000	170,000
Snowshoe	60,000	85,000
Totals	677,000	880,000

The figures for the first half of 1908 were: Granby, Company, 533,000 tons; B. C. Copper Company, 50,000; Dominion Copper Company, 2,000; total 585,000 tons. It should be noted that the B.C. Copper Company's mines were closed for several months in 1909, and for a shorter period in 1910, owing to labour difficulties. It is noteworthy that the tonnage for the first half of

1910 shows an increase of 30 per cent. as compared with the corresponding period of 1909, and of 50 per cent. with that of 1908, and this notwithstanding the long-continued low price of copper, which is the chief marketable metal contained in the ores of the mines under notice. Further, the indications are that the increased production will be continued.

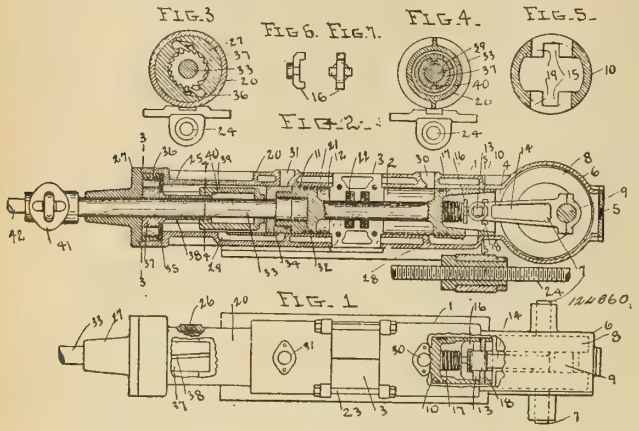
Turning now to Rossland mines, it is gratifying to find an increase this year as compared with the first half of last year, though the position is not favourable in comparison with the corresponding part of 1908. The decreased tonnage has been in the production of the Le Roi mine only, the two other important producing mines of Rossland camp, showing increases. The tonnage for the three half years, respectively, is shown in the following round figures:

Mines.	Tons. To June 30, 1908.	Tons. To June 30, 1909.	Tons. To June 30, 1910.
Centre Star Group	84,500	83,000	97,500
Le Roi	39,000	9,000	7,500
Le Roi No. 2.....	15,000	15,000	16,500
Others	500	500	500
Totals	139,000	107,500	122,000

The second-class ore milled at the Le Roi No. 2 concentrating plant, about 1,550 tons per month, is not included in the figures given in the table, which shows an increase of 13 per cent. this year over last.

The production figures for East Kootenay mines do not exhibit similar progress, for the quantity of lead-silver concentrate received at the Trail smeltery during six months of 1910 was but 9,000 tons, as compared with approximately 11,000 tons for the corresponding period of 1909, and 10,000 tons for 1908. However, this decrease is in part compensated for by receipts of about 6,000 tons crude ore from the Sullivan group mine; only in part, though, for there is of course considerably less lead and silver in crude ore from the Sullivan mine than in a similar quantity of concentrate from the St. Eugene, The North Star mine, also, has this year produced less ore than last. On the whole, then, East Kootenay's ore production shows a decrease for the expired portion of the current year.

In Ainsworth mining division, the mines that were the largest producers last year have not made so good a showing this year. In the Slocan there has been improvement, to some extent, in production, in much larger degree with development that gives promise of a substantially larger output of ore. The most noticeable increases were those of the Standard and Van Roi, on Slocan Lake, and the Richmond-Eureka, near Sandon. The figures for the Standard are about 600 tons of high-grade silver-lead ore this year, as against 400 tons for the first half of last year; those for the Van Roi are 700 tons of silver-lead concentrate shipped to Trail, and last winter's mill output of silver-lead concentrate (about 1,200 tons) in course of shipment to Oklahoma, U.S.A., as compared with no production at all during the first half of 1909. Then the record for the first half of three years, respectively, for the Consolidated Mining & Smelting Company's Richmond-Eureka group was as follows: To June 30, 1908, 900 tons; to June 30, 1909, 1,700 tons; to June 30, 1910, 2,200 tons; all of silver-lead ore, shipped to the company's smeltery at Trail.

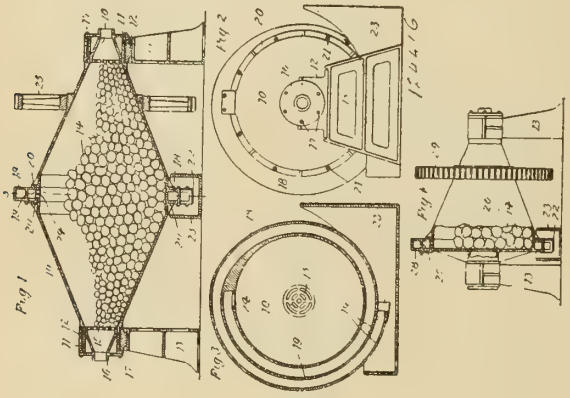


Incidentally, it may be mentioned, that the Silverton Mines, Limited, developing the Hewitt-Lorna Doone group, and the Van Roi and Standard, all in Silverton or Four-Mile Creek camp; the Ellis Silver Mining Company's Westmont, on Ten-Mile Creek, Slocan Lake; the Richmond-Eureka, Slocan Star, and Ruth-Hope groups, all near Sandon; the Surprise and Sunset, above Cody Creek; Rambler-Cariboo, in McGuigan Basin; Lucky Jim, near Bear Lake, Eastern Slocan; Whitewater group, in Whitewater camp, and Cork, on the south fork of Kaslo Creek, have each done development work which has made available more ore, and consequently considerably improves the prospect of increased tonnage during the latter half of the current year. In two or three instances the outlook is distinctly gratifying, so that it appears quite reasonable to look for a marked advance as a direct result of development work done in the mines.

In Nelson division there have been several increases in tonnage shipped, while the total quantity of ore put through stamp mills may also have been larger. The Queen Victoria, near Nelson, shipped about 700 tons of copper ore to Trail, as against none last year; the Silver King's production fell off 200 tons—1,600 as against 1,800 tons; the Yankee Girl, at Ymir, has 3,000 tons to its credit this year as compared with 500 tons to June 30th, 1909. Reliable statistics of gold-quartz ore milled are not available at present.

Other interior producing mines are the Silver Cup, in Lardeau district, owned by the Ferguson Mines, Limited, which usually maintains an average monthly production of about 140 tons of high-grade silver-lead ore, also containing gold, and the Hedley Gold Mining Company's Nickel Plate mine, which last year milled 31,000 tons of ore of an average value of between $12 and $13, and is now paying a quarterly dividend of 3 per cent. on its issued capital. Coast metal mines, as a rule, are not shipping ore; exceptions must be made in favour of the Marble Bay and Cornell mines, on Texada Island, both of which are stated to be returning profits to those operating them. There is development work in progress in other parts of the Coast district—on Howe Sound and in the country behind it; Valdes, Lasqueti and Queen Charlotte Islands; in several widely-separated parts of the Skeena River country, and elsewhere in the extensive region comprising what is comprehensively known as the Coast district. The part now attracting most attention is Portland Canal, in which district there are two mines sufficiently developed to give promise of proving productive, namely, the Hidden Creek Copper Company's big copper mine, on Observatory Inlet, an arm of Portland Canal, and the Portland Canal Mining Company's gold-silver-lead mine on Glacier Creek, a few miles from the head of the canal. The former has about 300,000 tons of copper ore in sight, and Mr. M. K. Rogers, of Seattle, Washington (well-known as the man who developed the Nickel Plate mine, near Hedley, Similkameen) states that $400,000 has been expended on the property and that it is intended to erect a 500-ton smeltery there before long. The latter has also had much development work done on it during the last two or three years, under the supervision of Mr .C. H. Dickie, of Duncans, Vancouver Island, director, who early obtained the advice of Mr. W. J. Elmendorf, M.E., of Spokane, Washington, who has since been engaged as resident manager. A concentrating mill is being equipped with the requisite machinery, and an aerial tramway, to connect mine and mill, is now in use. These two companies have done much work and little talk, and have consequently made material progress towards proving whether or not mining on a commercial basis, not on paper only, can be made a profit-earning industry in the Portland Canal district.

CANADIAN PATENTS.

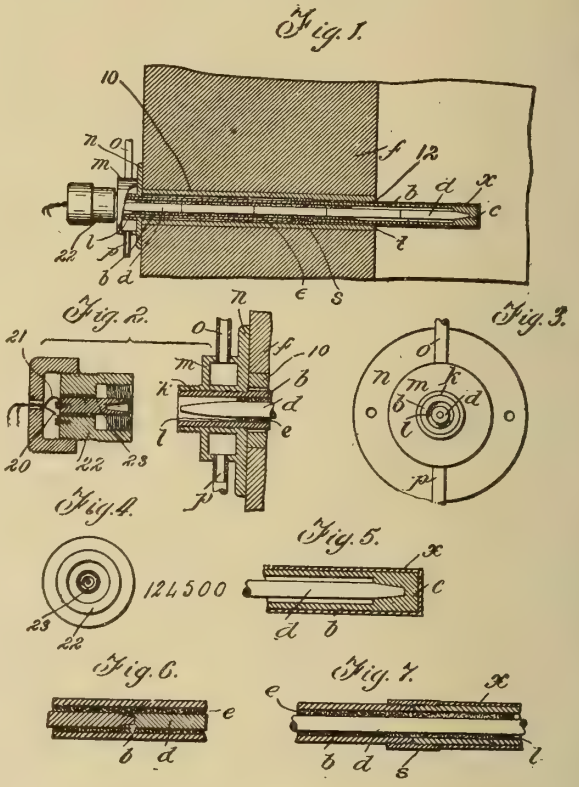


No. 124,360. Internal Combustion Rock Drill.
Foret à roc à combustion interne.

Lewis L. Scott, Joplin, Missouri, U.S.A., 8th March, 1910; 6 years. Filed 3rd November, 1909. Receipt No. 176,002.

Claim.—A motor drill comprising a pair of opposed two-cycle explosive engines including pistons mutually connected, a crank shaft connected with one piston, a drill rod connected with the other piston, and means for rotating the drill rod, said drill rod projecting from the corresponding engine, and the remaining removable parts of the motor drill being entirely enclosed within the cylinders thereof, etc.

No. 124,416. Pebble Mill. *Moulin à galets.*



Max Frans Abbé, New York City, New York, U.S.A., 15th March, 1910; 6 years. Filed 10th February, 1910. Receipt No. 179,598.

Claim.—1. A pebble mill comprising a coniform shell having a peripheral inlet opening at the widest portion thereof, a pair of supporting bearings, means for axially rotating the shell, grinding bodies inclosed within the shell, a casing encompassing the shell at the widest portion thereof, a spiral conveyer within the casing and communicating with the inlet opening, and trough into which said conveyor is adapted to dip.

2. A pebble mill comprising a coniform shell having a peripheral inlet opening at the widest portion thereof, a pair of trunnions, one of which is hollow, means for axially rotating the shell, grinding bodies inclosed within the shell, a casing encompassing the shell at the widest portion thereof, a spiral conveyer within the casing and communicating with the inlet opening, and a trough into which said conveyer is adapted to dip.

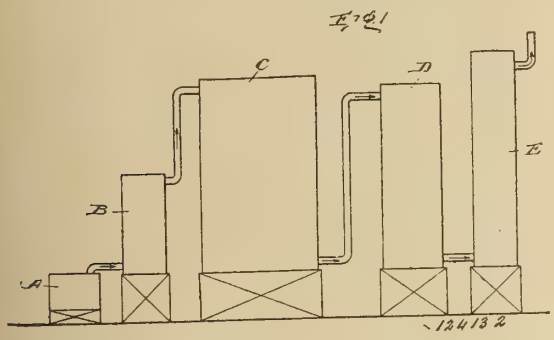
3. A pebble mill comprising a coniform axially rotatable shell having a peripheral inlet opening at its widest portion, grinding means inclosed within the shell, and a spiral conveyer encompassing the shell at its widest portion and communicating with the peripheral inlet opening.

No. 124,500. Thermo-Electric Pyrometer.
Pyromètre électrique.

Alfred Stansfield, Montreal, Quebec, Canada, 15th March, 1910; 6 years. Filed 21st December, 1907. Receipt No. 154,070.

Claim.—1. A thermo-electric couple comprising a graphite tube having therein an amorphous non-graphic carbon rod, substantially as described.

2. A thermo-electric couple one member whereof is of tubular form and the other a suitable conductor thermo-electrically different from and located within the tube, and a suitable electrical connection between such members, substantially as described.



3. A thermo-electric couple one member whereof is of tubular form and the other a suitable conductor thermo-electrically different from and located within the tube, the electrical connection between such members being within the tube, substantially as described.

4. A thermo-electric couple one member whereof is of tubular form and the other a suitable conductor thermo-electrically different from and located within the tube, such tubular member having its fire end closed and the inner member being supported at one end by the said fire end and at another point by an insulating device within the tube and spaced from the fire end, substantially as described.

5. The combination with a thermo-electric couple and the terminals thereof, of a portable plug containing the terminals of a pair of conductors, such plug being adapted to be attached at the end of the couple and effect electrical contact between the respective terminals, substantially as described, etc.

No. 124,132. Apparatus for the Manufacture of Sulphuric Acid.

Appareil à fabriquer de l'acide sulfurique

Frederic J. Falding, New York City, New York, U.S.A., 1st March, 1910; 6 years. Filed 19th November, 1909. Receipt No. 176,551.

Claim.—1. In an apparatus for the manufacture of sulphuric acid the combination of a source of sulphurous acid, a Glover tower, a lead chamber, having its vertical axis considerably exceeding any horizontal axis, cooling means for the reaction products and a Gay-Lusac tower, substantially as described.

2. In an apparatus for the manufacture of sulphuric acid the combination of a source of sulphurous acid, a Glover tower, a lead chamber having its vertical axis in the proportion of 3 to 2 for any horizontal axis, cooling means for the reaction products and a Gay-Lusac tower, substantially as described.

3. In an apparatus for the manufacture of sulphuric acid, a source of SO_2, a Glover tower, a lead chamber having a height so far exceeding its length and breadth as to allow relative zones of reaction and inaction to be formed therein, cooling means for the products of such reaction and a Gay-Lusac tower, substantially as described.

4. In an apparatus for the manufacture of sulphuric acid, a source of sulphurous acid, a Glover tower, a lead chamber having its vertical axis in the proportion of about 3 to 2 over any horizontal axis, and a Gay-Lusac tower, substantially as described.

5. In an apparatus for the manufacture of sulphuric acid, a lead chamber having a vertical axis substantially in the proportion of 3 to 2 over any horizontal axis.

6. In an apparatus for the manufacture of sulphuric acid, a single lead chamber having its vertical axis greater than any horizontal axis.

Carload lots of fluorspar from localities in Colorado, Kentucky, and Illinois, consigned to steel manufacturing centres, range from 96.01 per cent. calcium fluoride down to 60.9, the average being about 85 per cent. Silica contents range from 1.22 per cent. up to 27 per cent., although usually the percentage of this impurity is below 12.

BOOK REVIEWS.

THE COAL AND IRON INDUSTRIES OF NOVA SCOTIA, BY C. OCHILTREE MACDONALD; THE CHRONICLE PUBLISHING COMPANY, LIMITED, HALIFAX, N.S., 1909.

No question can arise as to the usefulness, timeliness and authoritativeness of this book. The author, Mr. C. Ochiltree Macdonald, has long been identified with Nova Scotia's mining development. He has for some years collected material. The volume before us is the result.

In Mr. Macdonald's review of the coal-mining and iron industries, he traces historically the growth of each. He also touches sufficiently upon the geology of the coal and iron ore deposits, upon present industrial and social conditions, and upon the general possibilities of the province. The investor will find much miscellaneous information that can be found in no other collected form. The general reader will discover many interesting bits of history. Except for the fact that the book is execrably printed, it is worthy of commendation.

CORRESPONDENCE.

Home Life Bldg, Toronto, Ont.,
July 6th, 1910.

Editor CANADIAN MINING JOURNAL,
Confederation Life Building,
Toronto, Ontario.

Sir,—The discussion in the Journal of July 1st with reference to the reduction of the percentage of oxygen in compressed air furnished by the Cobalt Hydraulic Power Company for power in mines, calls attention to the general question of mine ventilation.

In every mine in Cobalt, considerable time is lost by miners waiting for the workings to be cleared of fumes and gases produced by blasting. The amount of time thus lost is often considerable. There is also the loss in decreased efficiency of the miners because of constant bad air. Were these losses noted and itemized, the result would in many cases astonish the management, but like rich ore thrown over the dump, they are not accounted for and consequently are ignored. A system of ventilation by fans, or otherwise, is inexpensive to install and to operate, and would be paid for many times over during the year in increased efficiency and amount of labour, were the air pure.

Aside from the question of economics, the miner has a natural right to breathe pure air. Undoubtedly consumption and other diseases of the respiratory organs are contracted or stimulated by this impure air. It is little known how many men are carried to the surface unconscious because of breathing the poisonous gases incident to blasting, and many a man has been killed thereby.

In some mining districts compulsory ventilation is established by law, and I advocate that this be done in Ontario. No liberal-minded mine manager would oppose legislation which yields profit to his company, and is but justice to the miner.

Yours truly,

FRANK C. LORING.

Imports into Canada of ferro-manganese and spiegel amount yearly to about 18,000 tons, having a money value of considerably more than half a million dollars.

PERSONAL AND GENERAL.

Mr. R. B. Brinsmade, professor of mining engineering, University of West Virginia, examined several mining properties in the Lake of the Woods district during the latter part of June.

Mr. A. Erskine Smith, managing director of the Red Cliff Mining Company, Portland Canal, is now at the mine arranging for the development of a local water power to operate the plant.

Professor F. A. Thomson, head of the department of mining engineering of Washington State College, Pullman, Washington, lately sampled a "dry ore" silver mine in Slocan district, B.C.

Mr. A. J. McMillan, managing director of the Le Roi Mining Company, early in July, left Rossland, B.C., on a business trip to England. He will probably return to British Columbia in August.

On Wednesday, June 29th, Dr. W. G. Miller left Toronto on his way to Stockholm, Sweden, to attend there the International Geological Congress. Dr. Miller will first visit Scotland. He will probably join the excursion to Spitzbergen arranged by the Congress.

Mr. Charles T. Mitchell, who for several years has been construction engineer at the Granby Company's smelter at Grand Forks, B.C., at which large and important additions and extensions have been made, is now with the Canadian Copper Company, at Copper Cliff, Ontario.

Our readers will be interested to learn that Messrs. Keuffel and Esser have established a repair department at the Montreal office, 252 Notre Dame Street, West, Montreal. The new department will be fully equipped to undertake the repairing of all classes of surveying, drawing, and measuring instruments.

Mr. Peter Christianson, until recently one of the district mine superintendents of the Dominion Coal Company, has been appointed general superintendent of the operations of the Pacific Pass Coalfields Company, in northwestern Alberta. It is with genuine and unanimous regret that the workmen and officials of the Dominion Coal Company see Mr. Christianson depart. His record in Cape Breton is a remarkable one. Mr. Christianson is a Dane, and when he landed from a Norwegian sailing vessel over twenty years ago he was not acquainted with the English language. From the lowest position in a coal mine, Mr. Christianson has worked himself from overman to manager and from manager to superintendent, gaining at the same time a reputation for modest integrity which any man might envy. While Mr. Christianson's departure from Cape Breton will be a distinct loss to the mining community, he will be an acquisition to our western colleagues in his new position, and the good wishes of Cape Breton friends will follow him. Mr. Alexander MacDonald, for many years manager of Dominion No. 4 (Caledonia) Colliery, has been appointed as superintendent of No. 3 district in Mr. Christianson's stead. The new collieries at Lingan, now rapidly becoming an important part of the Dominion Coal Company's operations, are not included in the district allotted to the new superintendent, and it is said they will be constituted a new and separate district.

R. W. LEONARD.

Mr. R. W. Leonard, St. Catharines, Ont., has been appointed by the Ontario Government to fill the vacancy on the Board of Governors of the University of Toronto, caused by the death of Dr. Goldwin Smith. Mr. Leonard is the only mining man on the Board. The choice is a good one. For years Mr. Leonard has been closely identified with mining. He is a graduate of the Royal Military College, Kingston. Always an enthusiastic member of the Canadian Mining Institute, last winter he was elected to the position of vice-president. Fortune has smiled substantially upon him. He is one of the chief owners of the Coniagas mine, Cobalt, from which something more than travelling expenses is received annually. As president of the company, and of the subsidiary smelting concern at Thorold, Mr. Leonard has moulded the policies of both. Incidentally, he is a prominent member of the Canadian Society of Civil Engineers, a military enthusiast, an inventor in a mild way, and an all-round good citizen. The University is warmly to be congratulated.

Mr. H. Harris, formerly superintendent, under Mr. R. Hedley, of the Hall Mining & Smelting Company's smeltery at Nelson, B.C., and of the Brown Alaska Company's smeltery at Hadley, Prince of Wales Island, Alaska, is now general manager for the Tasmanian Smelting Company, Limited, at Zeehan, Tasmania, where he also has charge of two mines.

Dr. T. L. Walker, of the University of Toronto, was in British Columbia recently in connection with an investigation of the molybdenum deposits of Canada he is making for the Mines Branch of the Dominion Department of Mines, for the purpose of completing and publishing a monograph on this subject.

Professor Milnor Roberts, dean of the school of mines of the Washington State University, Seattle, lately again visited the coal mining district in Nicola Valley, B.C.

Mr. J .B. Woodworth has returned from a professional visit to Newfoundland, during which he inspected a large number of promising mining claims.

Mr. W. L. Coulson, of Somerset, Pennsylvania, formerly in charge of coal mines in Virginia, Kentucky and Pennsylvania, respectively, has been appointed general manager for the Canadian Collieries (Dunsmuir) Limited, which recently acquired the Wellington Colliery Company's collieries on Vancouver Island B.C.

Mr. James Ashworth, of Fernie, B.C., general manager of the operating department of the Crow's Nest Pass Coal Company, Limited, has been giving expert evidence at Victoria in connection with an action for damages brought on behalf of the widow and children of one of the 32 miners who lost their lives in the Wellington Colliery Company's Extension coal mines, Vancouver Island, when an explosion took place there last October.

Mr. E. Hibbert, for several years superintendent of the mines of the Le Roi No. 2, Limited, at Rossland, B.C., has succeeded Mr. Paul S. Couldrey as superintendent of the British Columbia Copper Company's Mother Lode mine, near Greenwood, Boundary district, B.C.

The annual consumption of coal in Canada is approximately 20,000,000 tons. Of this quantity the United States supplies slightly more than 50 per cent.

The annual consumption of coal per capita has risen in Canada from 0.758 ton in 1886 to 2.83 tons in 1908.

Since the year 1895, Canada's coal production has shown a steady annual increase. Since 1876, only during four years, namely, 1883, 1885, 1892, and 1895, has there been a falling off in annual outputs.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Dominion Coal Output.—The output of the mines for the month of June exceeded all expectations, being over 359,000 tons. This is 4,000 tons in excess of last June, and is a record for this particular month. Only on one previous occasion has the monthly output ever been larger than was obtained in the past month. This was in July, 1908, when the tonnage reached 368,000 tons. The prediction made in a recent letter that 16,000 tons would be reached in one day was justified in the last week of the month, for which the daily figures were as follows:

	Tons.
Monday, 27th	14,263
Tuesday, 28th	16,541
Wednesday, 29th	16,289
Thursday, 30th	13,824

These figures constitute a record for continuous production over several days. On one occasion, in 1904, the output for a day reached 16,600 tons, and in July, 1908, the figure of 16,359 was reached, but no four days in the company's history ever before yielded as much coal as the ones detailed above.

The output of the individual collieries was as follows:

	Tons.
Dominion	50,056
Number 2	67,944
Number 3	34,703
Caledonia	42,030
Reserve	33,904
Number 6	23,789
Hub	20,036
International	16,450
Number 9	35,357
Emery	13,876
Number 12	16,742
Number 14	3,476
Number 15	758
	359,121

It will be noticed that the new collieries at Lingan, namely Nos. 12, 14, and 15, contributed the respectable total of 20,000 tons to the general output. Owing to the incidence of the Dominion Day holiday with pay day, and Saturday the beginning of July showed much smaller outputs, and as there are fewer working days in July than last month it will be difficult to exceed the figures which were obtained in June, and the output will probably be about the same.

The Colliery Relief Societies.—The consolidation of the Colliery Relief Societies is now an accomplished fact, the Dominion Coal Company Employees' Benefit Society having commenced its corporate existence on the 1st of July. The election of officers and the details of organization will be completed at the first general meeting of the society, which is to take place on the 5th of July. The new scale of contributions and benefits becomes effective from the first of the month. Further details of the completed scheme will be communicated to the Journal probably in the next issue.

ONTARIO.

Cobalt.—The Beaver quarterly report for the period ending May 31st shows a cash balance of over $22,000. On May 4th a car of high-grade ore, assaying over 3,000 ounces, was shipped, but the returns are not included in the cash balance shown.

The annual statement of the La Rose will show a production for the past year of 3,150,000 ounces, which is a slight increase over 1908. In view of the action of the directors in cutting the dividend rate from sixteen to eight per cent., this production is, however, very encouraging. The company is paying dividends at the rate of $600,000 a year, so that there will be a very considerable amount to put into the cash reserve, which will ,it is believed, amount to nearly $600,000. Developments on the different properties are encouraging, particularly on the Lawson and Princess. On the former there are now two good ore shoots, on the No. 11 and No. 2 veins, that are producing high-grade ore. The Princess shows signs of becoming a steady producer, and is now in much better shape than formerly.

The Nipissing Company will sink two new shafts on veins discovered this season. One of these will be near the boundary of the Chambers Ferland, and the other near the Gillies Limit line, in the vicinity of Cart Lake. The latter is in the Keewatin formation, and very good silver values were found a short time ago. This company has declared its regular quarterly dividend of five per cent., with a bonus of two and one-half per cent.

The Little Nipissing has received word from the Peterson Lake Company that it has been granted a five-years' extension from the present date of expiry of its lease. This will mean that the Little Nipissing will have over seven years ahead of it, and the management will have more encouragement to go ahead and develop their holding. A decided improvement has taken place in the vein at the bottom of the winze at a depth of 225 feet. The vein is under and is carrying better values.

The management of the Haileybury Frontier Company has ordered a five-drill Canadian Rand power-driven compressor for its property in South Lorrain. This will be installed as soon as possible, as the work is badly handicapped for lack of power. The shaft is now down 125 feet, and will be sunk to the 150-foot level before a cross-cut is run to top the vein. Several promising leads have been found on the surface, and it was on one of these carrying good values in silver that the shaft was sunk.

Some time ago the Right-of-Way dump was purchased by several local people, and the first shipment from it has been made to one of the concentrators. The returns were very satisfactory, and the owners have decided to have the whole dump, which amounts to about 6,000 tons, treated.

In the Gillies Limit the Wyandoh is getting high-grade ore above the 110-foot level. Some values have also been encountered in a winze, on the same vein, to the east of the shaft. Some good ore is also being taken from the Waldman, and a winze is to be sunk on the vein from the bottom level.

The new Victoria vein, of the Crown Reserve, which was found on May 24th, promises to be one of the best yet opened upon the property. It is of good width, and carries remarkably high grade ore. From the 200-foot level a crosscut is being run parallel to the Kerr Lake line, which it is expected will open up the veins located by the diamond drill. The German government has become a buyer of Crown Reserve ore, and has contracted with the company to supply it 1,000,000 ounces. The ore will be very high grade, assaying approximately 4,000 ounces to the ton, and it will take about eight carloads to make up the required amount. The German government is operating a smelter and treating low grade ores, but as these were found to be too low to be profitable, they will be used in combination with that produced by the Crown Reserve.

A cross-cut from the bottom of the winze at the 280-foot level of the Cobalt Lake, has opened up the Morrison vein, When first cut it showed a number of small stringers, but when drifted on for about twenty-five feet, four inches of high-grade ore was encountered. It is expected that the Pellatt vein will also be caught in a short cross-cut from the 280-foot level.

The annual report of the Chambers-Ferland states that on May 15th, which is the end of the fiscal year, the company had cash on hand and ore in transit to the value of $117,217. Of this $14,400 has to be paid to the Ontario government as royalty. The gross value of ore produced during the year amounted to $130,968.24, and the total cost of production was $83,689.85, leaving a total profit of $47,278.39. On May 15th there were thirteen cars of ore ready to ship. These were medium grade,assaying approximately 250 ounces to the ton. The ore reserves are estimated at 240,000 ounces.

A very satisfactory report, issued by the Buffalo Mines, Limited, shows a general increase. During the year 33,708 tons of ore were hoisted, and all of this went to the concentrator. The average assay was 40 ounces to the ton, and an extraction of 78.60 per cent. was made. The production from the cyanide plant was 54,872 ounces, bringing the total extraction up to 82.67 per cent. Thirty cars of ore were shipped during the year, containing 654 tons of concentrates and 115½ tons of high grade. The concentrates averaged 1,570 ounces to the ton, while the average for the high grade was 3,126 ounces per ton. The total production for the year was 1,491,750 ounces, being an increase of 559,761 ounces over the previous year. The increase in profits was $197,723.89, while $142,000 in excess of the previous year was paid in dividends. There was also a very large increase in the ore reserves.

The following dividends will be payable during the month of July: McKinley-Darragh, three per cent. regular and two per cent. bonus, $112,348.85; Nipissing, five per cent. regular and 2½ per cent. bonus, $450,000; Right of Way, two per cent. regular, $29,971.08; Buffalo, five per cent. regular, $50,000; Crown Reserve, six per cent. regular and nine per cent bonus, $265,322.10.

Some rich ore has lately been found on the No. 16 vein of the O'Brien. On the 150-foot level the vein was practically barren, so it was decided to sink still further. When the winze was down a short distance, it passed into the diabase formation, and the values came into the vein again. The new shaft sunk through the mill, through which all the ore will eventually be hoisted, is practically completed, and will be in operation when the electric hoist is installed.

There are at the present time three cyanide plants in operation in this district, at the Buffalo, O'Brien, and Nova Scotia. The former was started last August and treats only the slimes from the concentrate. Since it has been in operation it has treated 6,424 ons of slimes, assaying about thirteen ounces to the ton, and containing a total of 83,034 ounces of silver. The total ounces recovered were 54,872, giving an extraction of 66 per cent. The Nova Scotia plant has been in operation only a short time, and, although good results are believed to have been obtained, no official figures are as yet available.

The Dominion Reduction Company has decided to erect a 100-ton custom concentrator on Kerr Lake ,to treat the low grade ore from that section of the camp. It is understood that arrangements have been made to erect the plant on the property of the Crown Reserve, and that this company's ore will be the first to be treated. The Cobalt Central mill in that section also treats custom ores, but the location is against its being used to any great extent.

The Lucky Godfrey Company, at Elk Lake, has lately been the victim of a most sensational high-grading case. Last April a car of ore was shipped from the property to the smelter at Thorold. It was supposed to have a value of approximately $40,000, but when the sacks were opened at the smelter they were found to contain low grade ore and waste rock, the whole car being worth a very small sum. It appears that several employees of the mine were implicated, and that before the ore left the property, the worthless material was substituted for the high grade ore. By this time it is probable that the ore is scattered all over the country and it is very doubtful if the company will be able to recover much of it.

At the Temiskaming mine high-grade ore is now being produced from two veins on the 400-foot level, one of the veins having been opened up from the shaft, while the other was picked up in a winze from the 350-foot level. The shaft has now reached a depth of 475 feet, and it is probable that another level will be opened up at this point. The new concentrator is running steadily, and is treating about 90 tons a day.

Ore is now being hoisted from the No. 3 shaft of the Trethewey, which was put down near the boundary of the Hudson Bay. The new concentrator is operating to full capacity, and is putting through between 80 and 90 tons a day.

Gowganda.—The first full thirty tons of ore to be sent out of this district by water, were shipped a few days ago from the Millerett Mine. This is somewhat in the nature of a trial shipment, and whether or not more will be sent out depends on the cost and the ease with which is can be handled. The ore had to be hauled over thirty miles by wagons, and then was transported down the river by boat. The roads are in very bad shape and teams can only haul from a thousand to fifteen hundred pounds a trip. No repairs have been made on the road since it was first built, but it is now expected that some of the prisoners from the jails at North Bay and other places will be sent in to keep it in shape. This high cost of transportation and the slight possibility of a railroad being built into the district makes it imperative that some method of concentrating the low and medium grade ores be used. The management of the Reeves Dobie has decided to put in a small plant, including two Nissen stamps. These will have a capacity

equivalent to an ordinary five-stamp battery, and will effect an important saving. It is probable that the Millerett will also install a somewhat similar plant in the near future.

Porcupine.—Excellent results have recently been obtained on the property of the Crown Chartered Company, and they now have better showings of free gold at a depth of seventy feet in the shaft than were originally obtained on the surface. As the different properties develop and larger plants are installed, as will be the case with several mines next winter, the question of power will have a more and more important bearing. The only fuel is, of course, wood, and the immediate supply of this will naturally decrease rapidly. In order to provide against this difficulty a syndicate of Montreal men has obtained the right of a water-power about forty miles distant from the centre of the district. Several engineers are at present engaged in making a survey of the power and an estimate of the cost of putting in a plant. The work of getting in supplies is becoming more difficult every day, on account of the low water. The rivers and lakes are falling rapidly, and it is thought that the gasoline launches will have to stop running very shortly, and that transportation by canoes will be the only method available. It is understood that New York capitalists are negotiating for a sixty per cent. interest in the Timmins-McMartin properties. They offer the present owners $1,000,000 and further agree to put $500,000 in the treasury for working capital, the only stipulation being that the owners complete the payments that are still due on the properties. It is doubtful, however, if this offer will be accepted, as the Timmins' contemplate forming a company of their own.

BRITISH COLUMBIA.

Mr. John B. Hobson has been preparing for hydraulicking on his placer-gold claims on the north fork of Quesnel River, in Cariboo district. He has been constructing a pipe-line about 3,000 feet in length, for the purpose of bringing in water for gravel-washing.

Zinc ore and concentrates are being shipped from Slocan mines to the United States. The Lucky Jim, Whitewater group, and Van Roi are the shippers. Mineral claims on Pingston Creek, in the Arrow Lake division of West Kootenay, are being prospected by New York men, who have bonded a group on which there are large showings of zinc ore.

A wagon road is being made from Phoenix to the No. 7 mine, Central camp, Boundary district. The Consolidated Mining and Smelting Company has between 40 and 50 men at work on the No. 7, to which a four-mile aerial tramway is being constructed, starting from the railway near Boundary Falls. A 10-drill air compressor, recently put in to supply power for this mine, is now in operation.

The "Fernie Free Press" lately published the statement that "the largest tonnage of coal in the history of the Crow's Nest Pass Coal Company's mines, at Coal Creek, was being mined there. On several recent days more than 3,000 tons of coal were taken out during twenty four hours."

The West Kootenay Mining Corporation, Limited, has been registered in London, England, with a capital of £125,000 in £1 shares, to adopt an agreement with Emissions Minieres, Limited, a French company, which had acquired the Joker and other mineral claims situated at the head of the south fork of Kaslo Creek, in Ainsworth mining division.

Announcement has been made that the Canadian Collieries (Dunsmuir) Limited, will open four new mines on Vancouver Island, two at Extension and two at Cumberland. Mr. Wm. Mackenzie, of Mackenzie and Mann, president of the new coal-mining company, has been credited with the statement that the company will, two or three years from now, be producing coal at the rate of 2,000,000 tons annually. At no time durnig the Dunsmuir (Wellington Colilery Company) ownership of these mines has their annual total production been as high as 1,000,000 tons—of late years it has been 700,000 to 800,000 tons.

At the first annual meeting of the New Dominion Copper Company, held a short time ago in New York, a statement was presented showing that wages claims against the old company, totalling $13,389, had been paid, and that diamond drilling in the company's Rawhide mine, and other expenditures during the fiscal year ended March 31, together with $26,938, had also been paid.

The lowest tunnel in the Lucky Jim mine, Slocan, which last December entered one of the large shoots of zinc ore that had been mined at higher levels, is now in the second big shoot of ore, distant between 800 and 900 feet from the portal of the tunnel. This development will largely increase the tonnage of ore available for shipment to the smelter. An aerial tramway from this low-level adit to the railway below, is being constructed, and other preparations for shipment of ore on a larger scale than in the past are also being made.

Slocan Lake.—In the western part of Slocan district, about Slocan Lake, mining is being carried on in several camps. The Mollie Hughes, near New Denver, has been sold to Vancouver, British Columbia, men. A recent discovery of ore on the Madonna claim, about three miles from New Denver, has been reported. The California, situated up on a mountain near the same town, has again been leased, and development work commenced; this mine gave a former lessee profitable returns from his operations.

There are some of the finest showings of ore at present to be seen in the Slocan in the faces of two drifts in the Standard mine, on Four-Mile Creek, near Silverton. In one level the lode is large—up to 30 feet in one place, with 4 to 5 feet of galena, in which also occurs fahlerz carrying high value in silver. The remainder of the lode is chiefly quartz with silver-lead and zinc through it. After the best ore is sorted out the remainder is placed on the dump to await the provision of concentrating facilities. Another level has a 12-foot lode, about one-third of which is shipping ore, and the rest of it concentrating material. Another level is being opened, at greater depth, and in this adit there are indications of the occurrence of ore which encourage the expectation that the valuable ore-shoot cut in the two levels above will also be found in this working.

About 100 men are regularly employed on the Van Roi, ore from which is concentrated at the Wakefield Company's mill, leased by the Van Roi Mining Company. Approximately 30,000 tons of ore have been mined and milled during the nine expired months of the company's fiscal year. Last year, to September 30, the output was 11,127 tons, but operations did not extend over a full year. Some 1,200 tons of zinc-silver concentrate, which accumulated at the mill during the winter months, is being shipped to Oklahoma, U. S. A.; it is expected this will bring the company $25,000, after payment of freight and smelting charges. The other mill product, a high-grade silver-lead concentrate, is sent to the Consolidated Mining and Smelting Company's smeltery, at Trail. The chief work being done in the Van Roi mine is on levels Nos. 3, 4, and 5, on the main vein, and on No. 4 in the south vein. The latest and most important and satisfactory results have been those from development work in the south vein. This was only recently reached, by a cross-cut from the main vein on No. 4 level. The ore has been found to be of good width, and assay returns from it have been excellent, so it is thought this vein will prove as valuable as the main vein from which latter a large tonnage has been mined and which has heretofore been the mainstay of the mine. More development work will have to be done, though, before it can be regarded as reasonably certain this hope will be realized. The work now in progress is further development preparatory to opening stopes. All the ore taken out in the course of drifting on this vein has been milled, but

stoping has been in the main vein only, and that above No. 4 level. There is equally good ore ready for being stoped on No. 5 level, but, as the portal of that adit is on the east side of the mountain, from which as yet there is no tramway connection with the Wakefield mill, no stoping has been done here. Nos. 3 and 4 levels are entered from the west side of the mountain, and the upper terminal of the tramway connecting with the mill is near the portal of the latter, while a "baby" tram provides a means for bringing the ore down from No. 3 to the terminal.

This mine gives employment to more men than any other in the Slocan, and its development is proving the existence in this part of Silverton camp of extensive and valuable shoots of ore, as has also been shown to be the case in other mines in the vicinity.

No ore has been shipped from the Hewitt-Lorna Doone group for several years, the policy of the Silverton Mines, Limited, the present owner, being to do much development work and block out much ore before commencing to ship. There is much silver-lead-zinc ore blocked out already, and lower levels are being opened to ensure a still larger tonnage before milling operations shall be undertaken.

Higher up Four-Mile Creek development work is also being done on the Fisher Maiden property, at which a tunnel is being driven at a lower level than that of the old workings.

The Westmont, on Ten-Mile Creek, is being worked by the Ellis Silver Mining Company. Some 25 men are employed, and the work in progress is reported to indicate that a productive mine will be established here. The Ottawa and Neepawa, both also in the Slocan Lake section of the district, are having work done on them, but with only a few men each.

Mr. Alfred McMillan has again leased the Velvet mine, near Rossland, to Mr. Ed. Ehrenberg, of Spokane, Washington. Some time ago Mr. Ehrenberg had a lease of this property, but, owing chiefly to the bad state of the road to the mine and consequent difficulty and expense of getting supplies in and ore out, he threw it up. Arrangements having been made to repair the road, he will try again to make the mine a profitable producer, and is sanguine he will succeed. Already men have been put to work, and development will be vigorously proceeded with. The ore is gold-copper, and the value of that shipped in earlier years was generally good.

A revival of interest in mining in the northern part of Fort Steele mining division, and in Windermere mining division, both in East Kootenay, is looked for as likely to result from the building of the Kootenay Central Railway, the construction of 30 miles of which is to be undertaken shortly. The Cranbrook Prospector expects the opening of a large mineral territory on the west side of Kootenay River, from Elk River north to Windermere. Along the route the new railway will take there are a number of mining properties on which much development work has been done and which have ore on the dump awaiting the provision of railway transportation facilities. It is quite probable a considerable improvement in matters connected with mining in the upper Kootenay and upper Columbia valleys, and along the valleys of creeks tributary to those larger streams will follow the opening of a railway through the district.

Up to May 10 the chief development work done on the Portland Canal Mining Company's Gipsy claim was as follows: No. 1 tunnel was in 225 feet; No. 2, 180 feet; and No. 3, 540 feet. An incline raise, 100 feet, connects Nos. 2 and 3. This constitutes the most development done on any claim in the camp. An aerial tramway, 8,500 feet in length, and 2,100 feet difference in altitude of its terminals, is in use. The first unit, nominal capacity 75 tons per day, of a concentrating mill is being equipped with the machinery and plant usually put in for concentrating ores containing silver and lead. This mill will be in operation before the end of August, unless something now unforeseen delays completion. A 6-drill air compressor is also being installed; it will be direct-connected to a Pelton water wheel. Water will be brought in a distance of 1,000 to 1,200 feet, and will furnish about 270 h.p. The Portland Canal Mining Company was the first to do much development work in the camp, and its management has from the first shown its bona-fide by mining in the ground rather than on paper only. It is satisfactory to know that with Mr. W. J. Elmendorf as resident manager, the property is under the direction of a competent and experienced mining engineer, so that it may be expected to be worked to best advantage.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax.—Mr. Justice Drysdale has granted an order in the case of the Cumberland Railway and Coal Company vs. McDougall and others, restraining the defendants and all members of the U. M. W. A., resident in Nova Scotia, from intimidating employees, and from watching places of business. The order holds until final judgment shall have been given in the trial of this action.

Halifax.—A lease of the Cumberland Railway and Coal Company's coal areas in Cape Breton, with option of purchase within that time for $500,000 to the Dominion Iron and Steel Company has been recorded. It is understood negotiations were opened when there was trouble between the Dominion Steel and Coal Companies over the coal supply for the steel works, and it was thought possession of the Cumberland Company areas would make the Steel Company independent as to its coal supply.

ONTARIO.

North Bay.—The property of the Montreal Reduction and Smelting Company, at Trout Mills, Ontario, is offered for sale by the liquidator. It is stated over $275,000 was spent on the smelter. It is not stated how much was spent in selling the stock of the company, which was being boomed here not so very long ago.

Sudbury.—The new stamp mill at Long Lake, belonging to the Canadian Exploration Company, was started at the beginning of last week and everything is running in a most satisfactory way. Ten stamps are in operation, and these, with the cyanide plant, will be experimented with and any desirable modifications noted. As the ore deposit is very extensive, the crushing capacity of the mill will be increased as required. Sudbury already feels the benefit of this new enterprise in its neighbourhood.

Long Lake.—The Canadian Exploration Company, Limited, made its first mill run at the plant at Long Lake during the month of June. As this is a private corporation details are not furnished, but it is understood that the new metallurgical process was very successful and that an extraction of 92 per cent. was obtained.

ALBERTA.

Coleman.—A discovery of platinum is reported near Coleman. The report has not been substantiated.

BRITISH COLUMBIA.

Hosmer.—The daily output of steam coal from the Hosmer collieries is 250 tons.

Phoenix, B. C.—It is probable that the Granby Consolidated Company will take options on some of the properties in the Franklin camp and develop them with a view to adding to the Granby ore reserves. O. B. Smith, superintendent of the Granby mines, has just completed an examination of several

properties on the north fork of the Kettle River, particularly those in Franklin camp.

The McKinley and Glouster are the particular groups of claims which Granby interests have under consideration. The McKinley has a tunnel in about 250 feet at a depth of 175 feet, and 115 feet of drifting. The property is owned by the McKinley Mines Company (Ltd.), which claims to have secured assays running up to 10 per cent. copper, 10 ounces silver, and $1 in gold. Close to the McKinley are the Ajax, Jumbo, I. X. L., Manhattan, and Gold King, all of which have good indications of ore.

The Glouster property is on the Banner Mountain, close to which are the Banner, Bullion, Mountain Lion, Alpha and Home Stake claims. The Glouster has a 50-foot shaft, and is said to have ore running 13 per cent. copper with $2.50 in gold and silver.

Franklin camp contains numerous deposits of self-fluxing sulphide ores, with values running from $8 to $40, and with the Granby smelter only 45 miles away there are good prospects for a flourishing camp.

Vancouver.—Material for the largest gold dredge in the world is now being shipped from Vancouver to Dawson. The plant will be installed on Bear Creek, at the mouth of the Klondike River. It is planned to have the hull of the dredge assembled and the machinery in place in time to make some test runs before the end of the present season, so that everything may be in shape to start permanent operations as soon as Bear Creek opens next spring. The dredge is owned by the Canadian Klondike Mining Company, which controls a large area of ground on Bear Creek. All the material entering into the construction of the hull of the dredge is being purchased in Vancouver. Over 500,000 feet of lumber will be contained in the hull of the dredge.

Victoria, June 30.—That the plaintiffs, Henry Croft et al., are entitled to registration of their option on certain coal lands was the ruling of Chief Justice Hunter to-day upon a point of law arising out of the suit of the aforenamed against Hon. James Dunsmuir, Whiting, Percy et al., for $4,600,000 damages. The suit stands over until after the vacation.

It is alleged that the defendants persuaded the owners of the lands in question to break their contract with the plaintiffs, and give a second option to Whiting which he attempted to register before the plaintiff's options were registered.

The lands in question are included in those ceded to William MacKenzie in the purchase of the Dunsmuir coal interests for $11,000,000.

Victoria.—Mr. R. W. Riddell, until recently manager of the British American Trust Company, with headquarters in this city, has been promoted to the position of managing director of the International Coal and Coke Company, Limited.

Mr. Riddell is well known locally, having for several years been manager of Saunders' grocery establishment and other commercial concerns here. He will now be stationed at Coleman, Alberta, the headquarters of the International Coal and Coke Company, in which concern A. C. Flumerfelt, of this city, is largely interested.

MINING NEWS OF THE WORLD.

UNITED STATES.

Los Angeles, Cal.—The bringing in of three more gushers in the Midway district has further complicated the oil situation and assures the further congestion of conditions in the field. With a few months in which to complete the storage and pipe line projects, together with the entering into new contracts with the railroads and other large consumers of fuel, who are inquiring into the merits of California oil, there is little doubt but that the present situation would be greatly clarified. But with the bringing in of more gushers the production is advancing with such gigantic bounds that many of the best informed oil experts are freely admitting that a policy of curtailment must be immediately inaugurated if the present price of the fuel is to be maintained.

Los Angeles, Cal.—Latest advices are to the effect that the Navy Department is considering the more extensive use of fuel oil for the American navy, now that a practically inexhaustible supply has been demonstrated in the California fields. The battleships Delaware and North Dakota, the two biggest fighting craft in the world, consumed oil for fuel in their trial trips, and the results have proven eminently satisfactory to the naval officers. The battleship Utah, the monitors Florida, Wyoming, and Arkansas, and some destroyers, have been equipped with oil burners in addition to their coal bunkers. Those in a position to know regard it as certain that the American warships will largely use fuel oil in the future, particularly when on the western coast. The recent completion of the Producers, Associated and Standard lines insures prompt deliveries of the oil to the government stations.

Cripple Creek, Colo., July 2.—The Cripple Creek gold district for June produced 61,515 tons of ore of the value of $1,249,302. The month was featured by the commencement of operations at the new mill of the Portland company on Battle Mountain. This plant uses the secret process invented by the company's employees and is handling the low-grade dump ores with success. Ore of as low an average grade as $2.46 per ton was put through the mill during the month, and the profit is said to exceed $1 a ton. No official figures as to the actual saving have been made public, though the amount handled is placed at 8,863 tons.

Boston, Mass., July 2.—What is believed to be the first move on the part of the Amalgamated Copper Company in an extended plan for the curtailment of its output has just been made in the discontinuance of all Sunday work upon its properties. Heretofore the mines have been working from one-half to one shift on Sunday, but now both shifts are laid off and the action taken means practically a 10 per cent. reduction in output.

Ely, Nev.—Since the inflow of water in the lower pit of the Nevada Consolidated last week two steam shovels have been working on ore on the level above, extracting on an average of nearly 9,000 tons of ore per day. A survey has been made for a new line of churn drills on the south of the pit, which will bring the machine to within 200 feet of the north line of the Chispa, owned by the Ely Central. The overburden in that section is heavy, and is growing heavier as the work progresses. But it is stated that the best grade of ore is now coming from that section of the pit. All of the ties and most of the steel have been laid for the railroad at the new steam shovel pit on the Liberty claim, a half-mile west of the old pit, but the shovels have not yet arrived.

Salt Lake City, Utah.—A body of ore 10 feet wide, which carries values of $28 a ton in copper and gold, has been cut by the long tunnel of the Utah Mines Coalition Company. It is the first material result to be obtained from the systematic campaign of development started by the company about 16 months ago, and its importance is not so much in the direct result itself as it is in the promise these indications afford.

Spokane, Wash., July 2.—Miners' Protective Association of Pine Creek has been organized by 30 operators and prospectors on the north side of the Coeur d'Alenes in Shoshone County, Idaho, to save the standing timber on mineral ground at its harvesting would injure the mining industry.

SOUTH AFRICA.

A cablegram from Johannesburg states that during May the mines of the Rand alone (i.e., excluding outside mines) crushed 1,785,821 tons. The average yield per ton was 28s. 3d., the working costs per ton were 17s. 6d., the profit per ton was 10s. 9d., and the aggregate profit 958,347 pounds. Compared with April (which contained one working day less) 22,717 tons more were crushed, the yield improved 2d. per ton, and as costs remained the same the profit was 2d. per ton more, and the aggregate profit was 31,103 pounds greater.

The annual report of the Transvaal Chamber of Mines for the year ended December, 1909, shows that while the number of stamps at work on the Rand only increased from 9,035 to 9,252 during the year, some 148 tube mills enabled the average duty per stamp to be increased from 4.86 tons per 24 hours in 1902, when there were no tube mills, to the average daily duty of 6.85 tons in 1909. The tonnage milled was equal to the capacity of 13,161 stamps of the 1902 capacity. In eight years the crushing capacity has increased by nearly 41 per cent, largely through the use of tube mill auxiliaries. Another feature of the return is the reduction in working costs. In January, 1908, the average for the Rand was 19s. 5d. per ton, and the average profit was 12s. 7d. per ton. In December, 1909, working costs had declined to 17s. 2d. per ton, while profits had only declined 1s. 5d. to 11s. 2d. per ton.

COMPANY NOTES.

NIPISSING'S DIVIDEND RECORD.

With the payment of the recent 7½ per cent., the Nipissing Mines Company will have disbursed to its stockholders the sum of $5,040,000 in cash since July 20th, 1906.

This does not include the amount paid by the operating company, the Nipissing Mining Company, Limited, to the syndicate prior to the above date, which amounted to about $400,000 between October 20, 1905, and June 20, 1906. Adding the amount to the surplus being carried by the company, of about $1,000,000, makes a total of $5,440,000 taken out of the property in less than five years, or more than the entire capital stock of the company at par.

While the company is in a position to increase its quarterly disbursements to stockholders, no such action is contemplated, but it is probable that interim dividends will be declared from time to time. It is stated on reliable authority that another interim dividend will likely be declared the latter part of the year, bringing the total amounts disbursed for 1910 up to 40 per cent.

The production of the Cobalt camp is expected to show a substantial increase over that of last year, which, in view of the advance in the price of silver, will mean gratifying increases in earnings of all of the producing companies. The output of both the Nipissing and the La Rose companies for 1910 are expected to be the largest in the history of the properties.

For the five months ended May 31 last the Nipissing Mines Company makes the following exhibit:

	Expenses.	Shipments.
January	$40,591	$187,114
February	35,966	174,528
March	47,300	214,785
April	37,371	216,192
May		208,537
Total, five months	$161,318	$1,001,156

THE NEW DOMINION CO.'S FIRST REPORT.

At the first annual meeting of the New Dominion Copper Company, held in New York recently, Newman Erb, vice-president, made a report for the fiscal year to March 31, 1910, as follows:

"The New Dominion Copper Company, on June 17th, 1909, acquired the property of the Dominion Copper Company, from the reorganization committee together with $347,999 cash. There having been no net earnings during the period, no payments were made on the income bonds on April 30.

"There was paid off $13,389 labour claims outstanding against the old company, while other expenses totalling $26,936 were incurred through diamond drill operations on the Rawhide mine for five months.

"An experimental contract has been entered into whereby the British Columbia Copper Company will treat 25,000 tons of our ores. Indications are that the New Dominion cannot furnish from 1,000 to 2,000 tons of ore daily, so that the erection of a new mill would not be justified."

John A. Sleicher has been succeeded as director by Clifford A. Chaffee, while at the first annual stockholders' meeting the following were reelected for the ensuing year: Newman Erb, N. Bruce Mackelvie, F. L. Sommer, Charles A. Starbuck, Lucius W. Mayer, who will be elected president, and W. W. Foster.

Le Roi No. 2 has paid $1,033,200 in dividends. This sum includes the dividend of 50 cents per share payable on July 8.

NEVADA CONSOLIDATED COST RECORD.

The Nevada Consolidated Copper Company, in the month of May, established a new record in cost per pound of copper produced. The net cost was 5.91 cents per pound, which bears out the contention of the management that the Nevada Consolidated can produce copper cheaper than any other mine in the United States.

The net earnings of the Nevada Consolidated for that month were $400,000, after depreciation deductions, which were at the rate of $4,800,000 a year. Nevada Consolidated is now paying at the rate of $3,000,000 a year in dividends.

Nevada Consolidated's world-breaking record in low copper costs was made in the face of the fact that only seven-eighths of the plant was in operation during the month of May. Production for the month amounted to approximately 6,000,000 pounds, which was at the rate of 72,000,000 pounds a year. Had the plants operated full, production for the month would have exceeded a rate of more than 80,000,000 pounds a year.

VAN-ROI MINING CO., LTD.

The following cable has been received by the London office from the company's managers at Rossland:

"Shipped during May, 220 tons concentrates.

"Received from smelter, $15,651 for 151 tons concentrates.

"Mill report for the month of May: Total amount crushed, 2,709 tons, yielding 120 tons lead concentrates, assaying 167.9 ozs. silver, 61.4 per cent. lead, 13.7 per cent. zinc; and 100 tons zinc concentrates, assaying 56.6 ozs. silver, 2.7 per cent. lead, 44.3 per cent zinc. Total approximate value, $14,169. Mill ran 533 hours.

"Estimated expenditure for corresponding period including mining, milling, development, and other expenses, $15,975.

"No. 4 level (main reef) advanced eastwards 70 feet. South reef: Near the hanging wall west of crosscut, advanced 70 feet, of which the first 40 feet, 6½ ozs. silver, 2 per cent lead, 11 per cent. zinc; width of 2 feet. For the last 20 feet ore in footwall. End of drive 66 ozs. silver, 3¾ per cent. lead, 14¼ per cent. zinc; width of 2 feet. Near the footwall 20 feet to the south, advanced east 22 feet and west 18 feet—promising.

"Zinc shipments delayed, shortage cars. Diamond drills finishing soon. Expenses will be less."

STATISTICS AND RETURNS

COBALT ORE SHIPMENTS.

Following are the shipments from the Cobalt camp for the week ending July 1, and those from January 1, 1910, to date:

	July 1. Ore in lbs.	Since Jan. 1. Ore in lbs.
Beaver	60,167	180,617
Buffalo	51,900	1,015,268
City of Cobalt	58,900	422,735
Chambers-Ferland	59,600	773,200
Cobalt Central		293,286
Cobalt Lake		260,900
Cobalt Townsite		68,000
Colonial		148,900
Coniagas		745,176
Crown Reserve	171,000	3,313,238
Drummond		664,200
Hargraves		101,800
Hudson Bay		241,435
Kerr Lake	300,600	4,920,416
King Edward	46,330	221,296
La Rose	79,800	6,315,541
McKinley-Darragh	135,440	1,623,639
Nipissing		5,407,337
O'Brien	110,040	758,086
Peterson Lake		330,710
Provincial		65,000
Right-of-Way		818,247
Silver Cliff		159,990
Timiskaming	120,000	921,830
Trethewey		503,950
Waldman		63,992

Ore shipments for the week ending July 1 were 1,193,777 pounds, or 596 tons.

Total shipments from January 1 to July 1 were 30,338,789 pounds, or 15,169 tons.

Following are the shipments from the Cobalt Camp for the week ending July 8th, and those from January 1st to date:

	July 8. Ore in lbs.	Since Jan. 1. Ore in lbs.
Beaver		180,617
Buffalo	55,400	1,070,668
City of Cobalt		422,735
Chambers-Ferland	64,000	837,200
Cobalt Central		293,286
Cobalt Lake		260 900
Cobalt Townsite		68,000
Colonial		148,900
Coniagas	120,480	865,656
Crown Reserve	213,420	3,526,658
Drummond		664,200
Hargraves	78,000	179,800
Hudson Bay	56,400	297,835
Kerr Lake	300,000	5,279,816
King Edward		221,296
La Rose	231,000	6,546,541
McKinley Darragh	55,830	1,679,469
Nipissing	347,930	5,755,267
O'Brien		758,086
Peterson Lake		330,710
Provincial		65,000
Right-of-Way	63,500	881,747
Silver Cliff		159,990
Timiskaming	80,740	1,002,570
Trethewey	87,900	591,850
Waldman		68,992
Wyandoh	48,300	48,300

Ore shipments for the week ending July 8th were 1,802,900 pounds, or 901 tons.

Total shipments from January 1st to July 8th were 32,201,089 pounds, or 16,100 tons.

BRITISH COLUMBIA ORE SHIPMENTS.

Nelson, June 25.—The ore shipments for the past week are decidedly satisfactory. Both the shipments and the smelter receipts for the first half of the year are now well over the million ton mark, an excellent showing indicating steady progress in the mining all over the Kootenay.

Appended are the details.

Property.	Week.	Year.
Boundary.		
Granby	23,014	609,092
Snowshoe	4,074	86,547

STEP REDUCTION

Wet or Dry

A mining Co. that has paid over $109,000,000 in dividends and is now mining 10,000. tons of ore per day, has contracted for the use of Hardinge Mills, and says, "It is the best fine grinding device we have ever gotton hold of."

HARDINGE CONICAL MILL CO.

37 Wall Street, - - - NEW YORK

Cable Address: Halharding, New York. Code: Bedford-McNeill.

MEN OF WEALTH

Are almost invariably the greatest believers in Life Insurance because they recognize the value of a "Cash" estate absolutely secured, and therefore they aim to maintain a considerable portion of their estate in the form of Life Insurance.

The North American Life Assurance Company appeals to business men because of its long record of success and its able and progressive management.

Assets, over $10,500,000. Net Surplus, over $1,000,000. Good Agency openings for energetic men.

NISSEN STAMPS

The Modern Independent Circular Mortar Gravity Stamp.

NORTHERN CUSTOMS CONCENTRATORS, Limited
COBALT, ONT., December 31st, 1909,

The Canadian Fairbanks Co., Toronto, Ont.

Dear Sirs :—

In answer to your inquiry regarding the Nissen Stamps supplied by your firm. These stamps are running steadily on some of the hardest rock on the Continent, they are crushing 5.3 tons of ore per head in twenty-four hours. The feed rolled down to go through about a one inch hole.

The screen used for the above tonnage was 30 x 30 mesh, 28 gauge wire, opening .018. With a coarser screen the tonnage would of course be larger.

The shoes and dies wear even, and the splash is well distributed over the screen.

The arrangements for keeping up the weight of the stamps are very good.

I can recommend the Stamps.

Yours truly,

(Sgd.) F. J. Bourne, Superintendent.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

GEOLOGICAL SURVEY

PUBLICATIONS

The Geological Survey has published maps and reports dealing with a large part of Canada, and with many local areas and special subjects.

MARITIME PROVINCES

The whole of Cape Breton, and a large portion of the coal and gold fields of Nova Scotia, have been reported upon, and mapped on a scale of 1 mile to 1 inch. The remaining portions of the Province, together with New Brunswick and Prince Edward Island, have been reported upon, and, in the case of the two latter Provinces, mapped on a scale of 4 miles to 1 inch.

QUEBEC

Quebec, south of the St. Lawrence, has been reported upon, and mapped on a scale of 4 miles to 1 inch. Many reports and maps dealing with portions of the Province north of the St. Lawrence are also available.

ONTARIO

A large part of the Province of Ontario, more particularly the northern and western portions, has been reported upon and mapped.

THE PRAIRIE PROVINCES

Geological maps and reports have been issued covering the greater part of the Provinces of Manitoba, Saskatchewan, and Alberta.

BRITISH COLUMBIA

The southern portions of British Columbia, as well as other parts of the Province, have been reported upon and mapped.

YUKON

Many of the important areas in the Yukon have been reported upon and mapped.

THE NORTH WEST TERRITORIES

Many reports and maps dealing with the outlying territory of Canada have been published.

Single copies of a report or map will be sent to Canadian applicants free of cost, and to others at cost of publication.

A complete list of publications will be sent free to any applicant.

Applications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA, ONT.

THE FOLLOWING GEOLOGICAL MAPS HAVE RECENTLY BEEN ISSUED:

CANADA

1084. General Geological Map of Canada. Scale 100 miles to 1 inch.

NOVA SCOTIA

1019. City of Halifax Sheet.
1025. Waverley Sheet.
1037. Windsor Sheet.

The above sheets belong to the regular series of Nova Scotia map sheets on a scale of 1 mile to 1 inch. The first includes Halifax City and Harbour, the second the Waverley Gold District, and the third Gypsum Quarries.

ONTARIO

1023. Geological Map showing position of Corundum-bearing rocks in Central Ontario.
1076. Gowganda Mining Division.
This map besides representing the geology of the Gowganda area, represents the geography of a considerable area to the east and north.
980. Portion of Algoma and Thunder Bay districts, Ontario, 1908. W. J. Wilson.
1081. Region lying north of Lake Superior between the Pic and Nepigon Rivers, Ontario, 1906. W. H. Collins.

BRITISH COLUMBIA

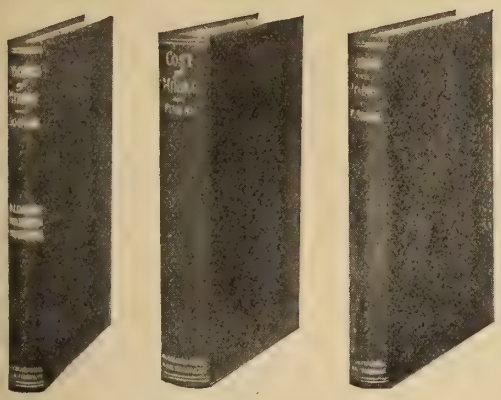
1002. Geological Sheet, Special Map of Rossland.
This map, on a scale of 400 feet to 1 inch, besides accurately indicating the topographical and cultural features, shows the geology and location of veins.
1004. Geological Sheet, Rossland Mining Camp. Scale 1200 feet to 1 inch.
1074. Sketch map of Sheep Creek Mining Camp, West Kootenay, B.C., scale 1 mile to 1 inch.

YUKON

1041. Geological and Topographical Map of Whitehorse Copper Belt. Scale 1 mile to 1 inch. Also several detail maps of same belt.

NOTE.—Maps recently published may be had on linen cloth, for use in the field, at 10c. per copy.

REPORTS



1072. Summary Report of the operations of the Geological Survey for year 1908.
1085. Descriptive Sketch of the Geology, and Economic Minerals of Canada. G. A. Young. Introduction, R. W. Brock.
1075. Gowganda Mining Division, 1908. W. H. Collins.
1035. Coal Fields of Manitoba, Saskatchewan, Alberta, and Eastern British Columbia, 1908. D. B. Dowling.
1050. Whitehorse Copper Belt, Yukon. R. G. McConnell.

NEW CATALOGUE

1073. Catalogue of Publication 1843—1909.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.

The Three Most Important Mining Books of Recent Years

They Cover

PRINCIPLES—ECONOMICS—METHODS

Principles of Mining. By H. C. Hoover, $2.50 (10/6) net postpaid.

The principles of mining as developed by modern science and business methods are here fully discussed under the general headings of Valuation, Organization and Administration. Important chapters cover investment from the public's standpoint, and the character, training and obligations of the mining engineer.

Cost of Mining By James R. Finlay. $5.00 (21s) net, postpaid.

An economic investigation of the cost of scientific, profitable mining. It contains valuable data obtained from official reports of the mines producing 75 per cent. of the metal under discussion. Detailed analyses cover cost of mining *coal, iron, lead, zinc, copper, gold and silver.*

Timbering and Mining. By W. H. Storms, $2.00 (8/6) net, postpaid.

Deals with practical methods, not theories. A straightforward account of the best, safest and most economical methods employed in the leading American mines.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The chief minerals of the Province of Quebec are: Asbestos, Chromite, Copper, Iron, Gold, Silver, Phosphate, Mica, Plumbago, etc; ornamental and building materials etc.

The Mining Law gives absolute security of title and aid to the prospector. It may be summarized as follows:

All mines belong to the Goverment of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

With the exception of lands already disposed of, the whole Province, in surveyed and unserveyed territory, is open to prospecting.

Miners' Certificates good for a calendar year may be obtained by sending $10.00 to the Department of Mines. Such certificates give the holder the privilege of staking out by himself claims to the extent of 200 acres, the minium being 40 acres in unserveyed land and one lot on surveyed Crown Lands, and part of a lot on private lands.

Such claim is valid for four months, without payment of any fee, and, within that time, the claim may be leased under a mining license, on payment of a fee of $10.00 plus a yearly rental of $1.00 per annum. No inspection of the discovery or assessment work is required.

The claim on unsurveyed land or the lot in surveyed territory may be purchased as a mining concession at the price of $20.00 per acre if within 20 miles of a railway in a straight line, or $10.00 if the distance is greater, and by fulfilling certain conditions mentioned in the law.

When the mines leased or sold are situated on private property, the land may be expropriated if the surface owner refuses to come to an amicable settlement with the holder of the mining rights.

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which discoveries of minerals have been made, and through which the new Transcontinental railway will run.

Special arrangements have been made with Mr. Milton L. Hersey, 171 St. James Street, Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners, and prospectors in the Province of Quebec.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the Province, and will supply maps, reports, copies of the law, tariff of assays, etc, to all who apply for the same.

All communications, letters and money must be addressed to

The Hon. Minister of Colonization, Mines and Fisheries.
Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

MONCTON, N.B.

Westinghouse

Type "H F" Polyphase Constant Speed Motors

Particularly adapted to mine service where the motors are required to start under severe conditions with a comparatively low starting current. Their design embraces the best possible balance of the various necessary operating characteristics:

¶ Air gap between rotor and stator to give safe operation for long periods without adjustment.

¶ Practically uniform efficiency between half load and 25% overload, allowing operation over a wide range of outputs.

¶ Provisions for free circulation of air, assuring cool operation.

Westinghouse "H F" Motors are made in standard capacities from 5 to 500 horepower (larger sizes built to order) for 25, 40 and 60 cycle operation:—See Circular 1152.

Three Post Magneto Electric Blasting Machine

NOBEL GELIGNITE

It always breaks cleanly to the bottom of the drill holes and is free from fumes of any kind. Equal to 75% Dynamite and is sold at a price producing very much better results in terms of Rock Broken or Extracted and money spent.

"WINTER BRAND" DYNAMITE

Is only one strength, if anything, a little stronger than 50% Dynamite. **It does not freeze,** or rather, explodes with perfect efficiency when frozen **and needs no thawing.**

"AUTUMN BRAND" DYNAMITE

Is packed in all the usual percentages. The powder is similar in appearance, character and effect to ordinary Dynamite, except that the freezing temperature of the Nitro-Glycerine is reduced from 42° F to a little under 30° F.

PERMITTED EXPLOSIVES for Coal Mines

A Ten-by-twelve Tent for $9.90

Made of 8-Ounce Duck

THIS is a photographic illustration of a special tent we have had made on a quantity-order basis. In no other way could we supply a tent of this size and quality of canvas for $9.90.

Made of 8 ounce duck, with double sewn seams and re-inforced strain points.

Used either with an outside ridge pole, or a ridge rope stretched between trees. An ideal prospector's tent with plenty of wall.

Dimensions—Height, 7 feet; Length, 12 feet;
Width, 10 feet; Height of walls, 3 feet.

Complete with guy ropes,..... **$9.90**

Poles and pegs if desired, **95c** extra

A "Black-Fly"-Proof Netting

A SPECIAL FLY NETTING with *smaller mesh* than the ordinary mosquito netting, so that it is proof against Black Flies, and all other insect pests. This netting we have had made to meet a special demand from the north country; per yard—9 cents, or piece of 24 yards for..... **$2.00**

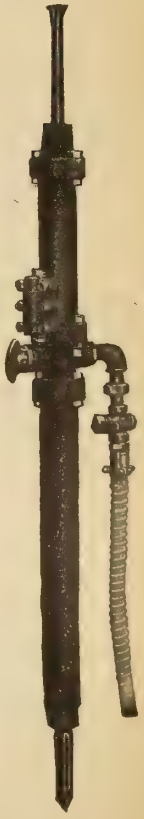
"CLEVELAND" STOPE DRILLS



EFFICIENCY:—Of course you want the stope drill which has the highest efficiency, but you must pick out the one that will have as high an efficiency a year from to-day. Isn't it true that your stope drills decrease steadily in efficiency as they grow older?

REPAIRS:—Repairs which must be made from time to time after the part has given long and satisfactory service, are not a source of dissatisfaction, but dont you find that your stope drills are constantly needing something new?

DRILLING CAPACITY:—As long as your stope drill will put in sufficient holes per shift to drill up your stope there is no argument in favor of your changing to our drill just because it will drill faster. We know that. But we know that the "CLEVELAND" Stope Drill will do as much work per shift when it is one year old as it will when one week old, and that is what you want, isn't it?

THE "CLEVELAND" Whether you purchase your stope drills after considering efficiency, repair cost, or drilling capacity, the "Cleveland" should be the stope drill you specify, for its design is such that the initial efficiency is the highest possible in an air tool, and the piston and valve action are so related that the "Cleveland" is just as efficient when it is a year old as when it is brand new; we **know**, and our information is gained from hundreds of installations that the "CLEVELAND" will cost less for repairs **per year** than any stope drill made; a 30 day trial will convince you that the "CLEVELAND" will drill as much per shift as any other stope drill, and we have machines always in stock ready to ship for trial if you will drop us a line, As you have everything to gain and nothing to lose, why not investigate NOW?

DIAMOND DRILLING VS. A SUBSTITUTE

The "justasgood" process of core drilling is advertised as much cheaper than the "real thing"—"just think of the high price of diamonds."

Nova Scotia is a locality, perhaps the only one, where diamond drills and the "justasgood" are used in the same formation, so that a fair comparison can be made of the two processes.

The following "Deadly Parallel" is made up from figures published in the report of the mines department for the year ending September 30th, 1909. *See Canadian Mining Journal for July 15th.*

DIAMOND DRILL		SHOT DRILL
3378	Total feet drilled	2198
$.79	Total cost per foot	$2.17
.58	Labor and management per ft.	1.17
.038	Diamond or shot loss per ft.	.057
13	Rate of drilling per shift in coal formation—feet	6

Sullivan Steam Driven Diamond Core Drill.

Please note, **first,** that the cost of diamond wear was **less** than the cost of shot wear, **second,** that labor cost is the heaviest item of all, and that shot drilling was twice as expensive as diamond drilling in this particular.

When **accuracy** and **reliability** are considered, the showing is much more in favor of the Diamond Drill.

Do you need drills or drilling work? Let us send catalogue 655, or make you a price per foot on testing your property by contract.

Amatite ROOFING

NEEDS NO PAINTING

MOST ready roofings require special painting and coating, and unless this is done regularly, you are sure to have leaks and trouble right along.

If you use Amatite, nothing of the sort is required. You will have real roof protection *without painting* of any kind.

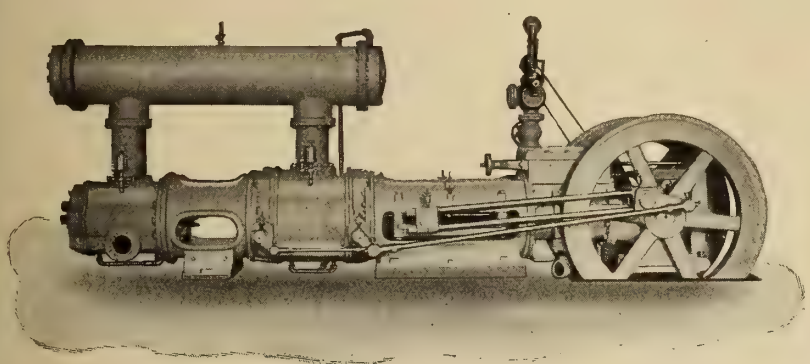
Amatite is made to stay waterproof and give protection year after year, without any thought or care on your part.

First—Because it is waterproofed with Coal Tar Pitch.

Second—Because it has a real Mineral Surface.

Amatite, owing to these features, is the most economical roofing made. Its first cost is low, and you are *saved* all future expense for repairs or paint because it will need neither.

If you haven't seen Amatite, write for a sample to-day. From it you will very quickly understand why it doesn't require painting; why it does not leak; and why it saves you money.



Address nearest office to-day.

Another Victory for the "DEISTER"

We are placing 180 Improved No. 3 Deister Slime Tables and 132 No. 2 Deister Sand Tables in the Miami Copper Company's mill, Miami, Arizona. This large order was the direct result of the showing made by the Deister Tables. The No. 2 Deister competing against all of the well-known makes of tables on the market—The Improved No. 3 Deister competing against vanners.

By eliminating teeth in the roller and rocker arm, our driving mechanism is now the most effective, noiseless and durable on the market.

THE

MINING MANUAL

1910

BY WALTER R. SKINNER.

The Standard Reference Work on Mines.

Price 17/- net Post Free (Abroad).

1,600 pages. In demy 8vo, handsomely bound in RED cloth.
A record of information concerning

MINING COMPANIES

(Gold, Diamond, Silver, Copper, Tin, Iron, and other Mines, Collieries, Land, Exploration and Mining Investment Concerns, &c.)

Arranged in three sections—

Australasian, African, Miscellaneous,

Preceded by Tables of Crushings and followed by lists of Mining

DIRECTORS, SECRETARIES, MINING and CONSULTING ENGINEERS and MINE MANAGERS.

Their Names, Addresses, and Descriptions, and Names of the Companies with which they are connected, and a

DICTIONARY OF MINING AND OTHER TERMS.

THE MINING MANUAL for 1910 contains particulars of over 3,600 Companies arranged in three sections, 430 Companies being AUSTRALASIAN (including Western Australia, Queensland, Broken Hill, Deep Leads, New Zealand and Tasmania); 1,030 AFRICAN (including Transvaal, Rhodesia ,West Africa, Cape Colony, Natal, Egypt); and 2,140 MISCELLANEOUS (including Siberia, Mexico, India, British Columbia, America, &c., and the Coal, Iron, Tin and other Mining concerns of the United Kingdom). The particulars given of each Company include the Directors and other officials; date of establishment; seat of operations; description of the property, with the purchase consideration; plant erected or in course of erection; present working results; ore reverses; details of capital; calls; dividends paid; and the financial position as disclosed by the accounts. Highest and lowest prices of the shares for the last four years, also latest price. The three sections extend over 1,100 pages,

Crushing tables and Gold Outputs from the principal mines are given at the commencement of the volume, showing tons treated monthly, results obtained, and yield per ton; also annual yields.

The Lists of Directors (8,000), Secretaries (1,900, Mining and Consulting Engineers and Mine Managers (1,400) include their addresses and descriptions and names of the Companies with which they are connected.

A complete Alphabetical Index, containing the names of 5,300 Companies and including many useful items of reference, occupies 42 pages.

Full particulars of all Re-constructions, Re-organisations and Amalgamations durlng 1909 are given in a simple and concise form.

"LINK-BELT" CONVEYING MACHINERY FOR COAL MINES

Retarding Conveyor, United States Coal and Coke Co. Anawalt, W. Va. Total length, in three sections, 1200 ft. Average capacity, 150 tons of run-of-mine coal per hour.

We Design and Construct:

Retarding Conveyors
All kinds of Chain Conveyors
Belt Conveyors
Car Hauls
Tipples
Coal Pockets
Bucket Carriers
Screw Conveyors
Picking Bands
Washeries
Coaling Stations
Power House Fueling Equipments
Lumber and Log Hauls
Car Loaders and Unloaders
Steel Casings
Rotary, Stationary and Shaking Screens
Conveying and Power Transmission Chains.
➢ FLINT-RIM ≺ Sprocket Wheels, Small Rollers and Truck Wheels for Conveyors, Carriers and Cars
Industrial Cars and Tracks
Steam and Electric Locomotive-Cranes
Chutes
Hoppers, Feeders
Weigh Boxes, Crushers
Elevator Boots, Buckets
Bearings
Takeups
Friction Clutches
Jaw Clutches, Etc.

We have issued a revised edition of our Book, copies of which will be sent to any address you specify.

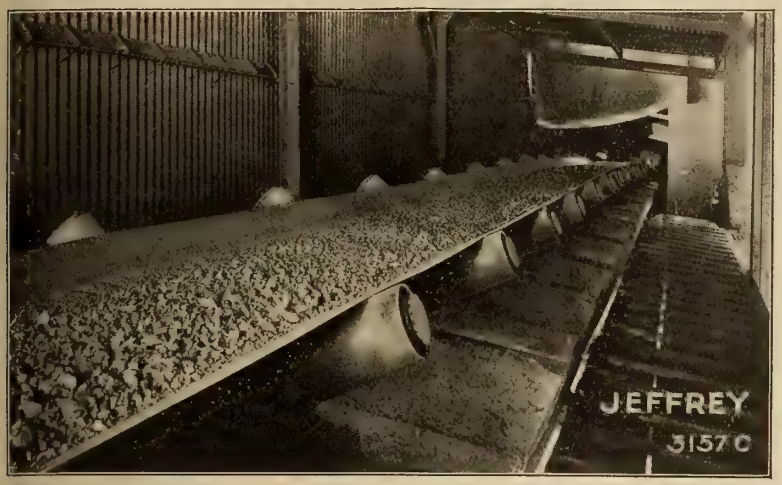
CYANIDE HANDBOOK BY J. E. Clennell



Over 500 pages, 6x9, illustrated, $5.00 (21s) net, postpaid

Mr. Clennell has been in close touch with the rapid developments of cyaniding. He has been instrumental, too, in many important discoveries, and his work in this field has taken him to the leading plants of the world. It deals generally with Cyanide and does not confine itself to the process alone. It is divided into nine main parts covering the subject more fully and exactly than it has heretofore been handled.

Especially noteworthy is the full treatment of recent developments and important phases heretofore *inadequately treated.*

THE TWO FUNCTIONS OF RESCUE APPARATUS.

Although rescue, or breathing, apparatus was primarily designed for the salvage of life after explosions in collieries, yet in practice the devices have been more utilized in fighting fires.

Experience has thus taught us the underlying principle, namely, that the provision of rescue apparatus for fighting fires in mines is a matter to be left in the hands of mine owners, but that the salvage of life after explosions, or in circumstances involving great danger to the rescuers, is one that concerns the Government more than the individual owner.

This principle has been recognized by the Home Secretary of Great Britain. In effect it has been acted upon by several Canadian collieries. But our Governments, both Provincial and Federal, have been exceedingly tardy in taking any steps whatever.

As matters now stand, those of our collieries that possess rescue stations may be called upon at any time to furnish assistance to other mines. This is absolutely unfair. In rescue work there is always a large element of risk. That risk is unreasonably large when the rescuers attempt salvage work in mines with which they are unacquainted. Indeed, it is debatable if such requests should be granted.

In these circumstances it is manifestly the duty of the Federal Government, and equally the duty of the Provincial Governments, to see to it that all coal mining centres are provided with the means of instructing coal miners in the use of rescue apparatus. Whilst mine owners must do their part, the Government cannot afford to ignore the moral obligation resting upon its own shoulders.

The subdivision of responsibility as indicated above forms the only practicable basis upon which joint work can be begun.

THE PASSING OF LE ROI.

There is something unspeakably tragical in the failure of a full-grown mining enterprise. Some years before the Rossland boom began, two French-Canadians, Morris and Bourgeois, staked the Le Roi claims. In 1892, Col. I. N. Paton, of Spokane, Washington, took over the mine. In 1893 extensive development was commenced. One year later the meteoric Augustus Heinze came on the scene. He it was who built nine miles of railway from the mine to Trail; also he erected a smelter wherewithal to treat the ore. Just after the height of the boom, ex-Governor C. H. McIntosh, known to all adult Canadians, came on the scene as a representative of one of Whittaker Wright's syndicates. After purchasing Le Roi for a sum exceeding $4,-000,-

000, the syndicate undertook to develop and prospect the property on a scale that was, perhaps, hardly warranted. A smelter was erected at Northport. Diamond drilling was begun, and sinking and driving pushed vigorously.

At least $20,000,000 in gold has been taken out of Le Roi. For some reason—there are those who assert that the mine has suffered from a surfeit of London management—Le Roi has never yielded continuous profits. In any case, its tenuous existence has been brought to a close. And simultaneously expire the hopes and expectations of many hundred unfortunate shareholders.

TO THE INVESTOR.

The mining boom serves a special purpse. It advertises the country, it stirs men to abnormal activity, it induces the circulation of enormous sums of money. These are its benign aspects. We need not dwell upon the other side of the shield.

But, psychologically, the mining boom leads men astray. Currents and gusts of enthusiasm sweep the investor off his feet, he follows the crowd, and, usually, is lost. . . .

We have recently returned from a visit to Eastern Canada. In those parts precious metal mining is supposedly dead. Despite this popular impression, we feel safe in stating that nowhere in Canada are there more numerous and more easily available opportunities for making legitimate profits in mining of all kinds.

It were unseemly to be too specific. We should hardly care to be the moving cause in a wild rush to the east. But it is at least impressive to run over the list of minerals that are known to exist in workable quantities. That list includes tungsten, gold, antimony, manganese, gypsum, barite, infusorial earth, talc, copper, and iron. Prospects of tin are known. Throughout certain portions of Quebec alluvial gold awaits modern investigation. It may be asserted without fear of contradiction that nowhere can the investor acquire promising property more cheaply and nowhere can he, in the main, get a better run for his money.

THE GEOLOGIST AND HIS GLIM.

Many centuries ago a Chinese prophet brought upon himself the scorn and contumely of a younger generation because he refused to commit himself to an opinion concerning the future life. To-day that prophet's name is still revered. His critics are lost in the beneficent obscurity of the ages.

The modern analogue of the Oriental prophet is the geologist. His business in life is to make a commercial diagnosis of scenery. So varied and so open to various interpretations is the evidence of nature that the geologist must often halt and stumble. Hence he gives the young scoffer his opportunity. And from all sides we hear shrill voices rising against the geologist.

Whilst we shall refrain from expressing our own opinion as to the ultimate value of the geologist, we shall not miss the chance of expressing our sincere sympathy for him. His is a most distressing lot. His mistakes are chalked up against him for all time. His achievements are not remembered. Is it possible that he should be more dogmatic? Is it probable that he obscures his light under a bushel of technical terminology? Perhaps, and we make the suggestion in all due modesty, perhaps if the geologist were to talk to us in words of one syllable, all of us would be happier.

THE TECHNICAL EDUCATION COMMISSION.

The universal tendency to sneer at Royal Commissions has not been so marked in the case of the recently appointed Federal Commission on Technical Education. Sneers there will be, but we believe that all serious citizens hope and expect excellent results from the work of this latest Commission.

The cordial welcome extended by the city of Halifax, when the Commission's labours were formally opened, was a most auspicious start. Without undue loss of time the Commission tackled its proper work, the work of collecting facts, figures, and opinions, as to the educational needs of this country. At present the Province of Nova Scotia is being covered. Later the whole of the Dominion is to be worked over.

We believe that from the array of evidence to be collected by the Commission many valuable facts will emerge. Its final report should be a document of great significance. But we are yet firmly of the opinion that the Commission lacks balance, inasmuch as its membership comprises no representative of the mining industry.

This omission can easily be rectified. The point should be pressed upon Ottawa insistently and unremittingly.

THE HAMMER DRILL.

One of the most interesting of recent papers is that entitled "Hammer Drills in Overhand Stoping and Raising." As the author, Mr. H. B. Williams, gained his experience in a Canadian mine, the paper has a particular claim upon our attention.

The comparative merits of the reciprocal and of the hammer drill are not yet determined. Much can be said on both sides. Probably both types have been unfairly criticized. But the fact appears to be established that the hammer drill is a necessity in narrow stopes. Mr. Williams' statement of comparative costs is startling, and his general assertions as to the efficiency of the hammer drill are most radical.

EDITORIAL NOTES.

From the Quebec asbestos regions come reports of much activity. Within a short time four new mills have been put in operation, one at Black Lake, one at Thetford, and two at Robertson. Labour is plentiful, and no shortage is expected.

On June 1st, 1911, the taking of the next census of Canada will commence. It is to be hoped that all concerned in the mining industry will do everything possible to aid the census-taker. It is of prime importance that the industry be given proper recognition.

By late advices we learn that proclamation has been made of new Coal Mine Regulations in the Province of British Columbia. These call for the provision by owners of coal mines of adequate rescue apparatus, supplementing the Government stations and trained rescue crews.

The "Daily News-Advertiser," Vancouver, supports the CANADIAN MINING JOURNAL in its remarks upon the failure of the Minister of Labour to see that the mining industry was represented on the Commission on Technical Education. Our contemporary reminds its readers that the matter is one that should appeal with especial force to citizens of British Columbia.

Several correspondents have drawn our attention to the fact that Hon. Mr. Templeman has failed to evince practical interest in the establishment of rescue stations. As the Hon. Mr. Templeman has pledged his word definitely to support this movement, we are disappointed at his indifference. We suggest that a prod or two from mine operators would do no harm.

GROWTH OF STEEL OUTPUT IN CANADA.

The growth of the pig iron production in Canada, as well as that of the Dominion Corporation, since 1901, is clearly shown in the following table:

	Total for Canada. Tons.	Prod. of Dominion Steel Co. Tons.
1909	609,400	255,900
1908	686,800	262,800
1907	416,600	257,000
1906	585,400	210,100
1905	390,200	162,200
1904	277,700	96,600
1903	323,700	155,130
1902	348,600	191,000
1901	165,900	111,000

The above figures show that the company has increased its production of pig iron from 111,000 tons in 1901 to 262,800 in 1908 and 255,900 in 1909, the slight loss in the latter year as compared with 1908 being due to the inadequacy of the fuel supply received from the Dominion Coal Company. The output of steel ingots has been as follows:

	Total for Canada. Tons.	Prod. of Dominion Steel Co. Tons.
1909	570,600	296,750
1908	662,000	279,500
1907	606,500	269,000
1906	569,200	235,300
1905	300,400	163,150
1904	128,900	62,850
1903	260,600	135,300
1902	136,400	99,400
1901	33,300	.....

The Dominion Company began to turn out steel in 1902 when it totalled 99,400 tons, increased since then to 296,750, an even greater gain than that recorded in the pig iron production.

The Government bounties on pig iron and steel ingots expire on December 31st this year, and those on wire rods, which were given in lieu of tariff, on June 30, 1911. It is thought that when the different bounties are terminated they will be replaced by a protective tariff, although the cessation of the bonuses indicates that the steel industry in Canada is thought to have established itself upon a firm and lasting foundation.

To take care of future business, the corporation has been carrying out extensive plant alterations and improvements, which will also materially reduce productive costs and increase the total capacity 50 per cent. The first new work to reach completion is the set of coke ovens which embody all the improvements of the last ten years. There are 120 of these, requiring the service of 56 men and capable of turning out 720 tons of coke every 24 hours. The 500 old ovens produce about 1,250 tons of coke a day.

Following these the open hearth furnaces will be finished and will be among the largest in the world, with a capacity of 500 tons each. A new power plant is under way, as well as a finishing plant, which will consist of a continuous roughing mill and Belgian train.

These improvements were provided for in the consolidated mortgage bonds issued last year, about $2,285,000 of the $5,000,000 total being set aside for the purpose.

During the past four seasons, net earnings have averaged about $2,327,715 a year, but after the different betterments have been completed the income account ought to show a gain corresponding with the greater capacity.

PERSONAL AND GENERAL.

Mr. H. E. T. Haultain has opened an office at 41 National Trust Chambers in connection with his work as consulting mining engineer.

Early in July Mr. A. A. Hassan left Cobalt for Porcupine. His visit to Porcupine will probably cover the whole month.

Mr. Edward Slade, who was recently manager of the Amalgamated Asbestos Corporation's properties at Black Lake and prior to the merger was manager of the British-Canadian Asbestos Company, has, it is understood, been appointed general manager of the Black Lake Consolidated Asbestos Company. This appointment is considered by the Black Lake Company to be an especially satisfactory move, as Mr. Slade has a high reputation in the asbestos industry.

EARLY COPPER MINING IN THE PROVINCE OF QUEBEC.

By James Douglas, LL.D., New York.

(Canadian Mining Institute, Annual Meeting, Toronto, 1910.)

Sir W. E. Logan, in his report for 1847-48, as Director of the Canadian Geological Survey, refers to copper in the Eastern Townships, and states: "The quantity appears to be too insignificant, in any case, to be worthy of further notice, with the exception of three deposits, where the ore, occurring in veins bearing the character of regular lodes, seems to be sufficient in amount to justify the risk of small careful trial. . . One locality is on the 4th lot of the second range of Inverness, in the occupation of Mr. George, where, on the east southeast side of a valley not far from the position which would be in the direct run of the associated serpentines and dolomites of Leeds and Inverness, a vein of opaque white quartz occurs in chloritic and talcose slates, and, coinciding in its direction with the strike of the measure, maintains with the valley a course a little to the north of east. The quartz vein, a mixture of chlorite, presents the thickness of about two feet, and the ore is disseminated in it in irregular patches and lenses, some of which weigh upwards of a pound; but the patches at the outcrop, in the spots experimented upon, are so thin that, notwithstanding the product of the pure ore, which is variegated copper, is upwards of 60 per cent., the whole two feet of the lode do not yield more than 0.74 per cent cwt., which would not give more than 90 pounds of copper in a fathom forward by a fathom vertical."

Nevertheless, it was on this not very flattering showing that the Megantic Mining Company was organized soon after the date of Sir William's report. The company secured other copper lands in New Ireland and Halifax Townships, and it still exists—the only survivor of the many organizations chartered in those early days.

My personal recollections are of spending my summer holidays of 1850 at these mines in Inverness. I recollect my father finding one of the shareholders reading by the light of a candle stuck into the blasting powder of an open keg, and another calculating seriously on the best way of disposing of his enormous prospective fortune and deciding on patriotically paying off the British national debt.

The copper deposits of Inverness which were then worked resembled the small rich gash veins which were subsequently opened more extensively in Leeds, but which proved in both places too unproductive in quantity to support a mining organization. I do not think the George veins were ever found to be associated with interstratified beds, though further development may show that such connection exists.

Some desultory work was done in Inverness as late as 1856.

The discoveries in the neighbouring Township of Leeds had withdrawn attention from those of Inverness. The same promoters and stockholders were interested in both. Dr. Douglas, when in England in the spring of 1853, interested the firm of John Taylor & Sons sufficiently to induce them to send out the well known mining and metallurgical engineer, John Arthur Phillips, to report on this prospect. I have not the report he made to them at that date; but in 1856, when the Quebec and Saint Francis Mining Company was organized to purchase and work the mine, Mr. Phillips supplied the company with the following statement:

Report of the Mines of the Quebec and St. Francis Mining Company.

"The lands acquired by the Lower Canada Mining Company in the Township of Leeds, County of Megantic, visited by me in company with Captain F. Kent in 1853, are principally composed of talcose chloritic and micaceous shales, of which the stratification in some localities is disordered, but has a general run approaching east and west. Their underlie, though variable in amount, is almost without exception towards the north.

"At Harvey's Hill, to which the attention of the company has been chiefly directed, a large mass of steatite crops out on the southeastern side of the concession. This substance contains in many places crystals of carbonate of iron; numerous specimens of asbestos were also remarked, and some of the shale beds contain large radiated masses of crystallized hornblende.

"The whole of this district is traversed by courses of white opaque quartz, which vary in thickness from a few inches to several feet. These in some instances appear to follow the general direction of the stratification of the country, whilst in others they are evidently true lodes intersecting the surrounding strata at a strong angle.

"Such veins in some cases contain copper, specular iron and arsenical pyrites, but are seldom accompanied by any considerable amount of gossan.

"The shale in the neighbourhood of these veins frequently contains well-defined crystals of iron pyrites. The general run of the true veins is about 30 degrees east of north, whilst their underlie, which is extremely variable in amount, is usually towards the west.

"In the Harvey Hill property at least five of these veins occur, and are all more or less spotted with spathose iron and grey copper ore. In addition to the veins above mentioned, and which vary in thickness from eight inches to three feet, this locality exhibits branches of rich copper ore.

"On arriving on the ground we found that with the exception of some very ill-directed shoading, no mining operations of any description had been carried on, and that these veins had been merely opened to such an extent as to admit of the extraction of some barrels of ore, which were forwarded to London.

"After having completed our general survey of the whole district, we set two men to open on the backs of the branches before mentioned. That called the Brook Lode was thus uncovered for a distance of about ten fathoms, and found to run thirty degrees east of north, with an underlie of one and a half foot in a fathom towards the northwest.

"At both extremities of the cutting, which was nowhere above four feet in depth, very excellent stones of grey copper ore were extracted; but towards the middle of the opening from two to three fathoms of unproductive ground were found to occur.

"We raised during our operations at this place eight cwt. of very fine copper ore, which was brought down to Quebec and forwarded to London.

"This lode, which at the time of suspending our operations was evidently improving in the eastern end both in size and produce, was again cut by an open drift about eighty fathoms south of the point last mentioned.

"In this locality, although much disturbed, very beautiful stones of horse-flesh ore are found, it being from this place that the finest specimens sent to England were procured.

"About twelve fathoms to the east of the foregoing vein, another rich branch of copper ore was discovered and partially explored previously to our arival. This vein could be traced for a considerable distance at the surface, and was opened on, for a length of about six fathoms, and a depth of some five or six feet, but although producing in some places exceedingly rich stones of copper ore, we found it very much disturbed and contorted, and regret to say its aspect was not materially improved by the workings we ourselves made upon it.

"In addition to the two branches of ore above described, a third was discovered on the Harris Lot, at a distance of little more than a mile to the southwest of the other. This lode, which occurs in a channel of highly magnesian shale, we opened on the back for a distance of about five fathoms and to a depth of eight feet, and in doing so obtained nearly one and a half ton of rich sulphuret of copper, slightly intermixed with crystallized carbonate of iron.

"The Harris Lode, as this vein has been called, was found when first opened, to be extremely rich in copper ore, and in fact still remains so; but although it evidently increases in size in proportion as it goes down, the ore last obtained was perhaps more mixed with carbonate of iron. This vein runs nearly north and south, and underlies towards the west, but from the slightness of the dip, together with the contortions to which the enclosing rock has been subjected, it is difficult to determine either its direction or the nature of the underlie it may ultimately assume.

"The other lodes in the district have, without exception, remained totally unexplored, since from the limited time allowed for the inspection, we were obliged to confine our operations to such veins as afforded the most favourable indications. It is, however, certain that numerous other true veins occur in this district, and that wherever exposed they almost without exception contain more or less copper ore. On the other hand it may be remarked that many bands of spar interposed between the layers of the strata, also afford copper, and that these are in some cases cut off in depth.

"The ores obtained from this property in 1853 yielded thirty-nine per cent. of copper, and were sold at the rate of £42 10s. per ton.

"In the month of September, 1855, this district was visited and inspected by Captain Francis Bennetts, who remained a longer time on the ground, and more fully explored the different lodes than had been done two years previously by Captain Kent and myself.

"At a distance of fifteen fathoms northwest of the opening on the Brook Vein, Captain Bennetts discovered a lode about twenty inches in width, bearing a little west of north, and on this he extended an open cutting six fathoms in length and eight feet in depth. At the time the workings at this place were discontinued, the lode in the bottom was from fifteen to twenty inches in width, without any perceptible underlie, and composed of a mixture of quartz, carbonate of iron, and grey copper ore.

"The lode in this excavation will for a distance of about two fathoms yield one ton of copper ore per fathom. In the other portion of the cutting the lode has been slightly disordered by a small band of killas. There can be but little doubt, however, that it will again yield ore a few feet beneath the point at which the killas has passed through it.

"Nine tons of ore, yielding from thirty-six to forty-two per cent. of copper, were raised from this cutting by two men in the course of four weeks. The Harris Lot, which was also explored, presented a regular lode about one foot in thickness. About two tons of ore were extracted from this vein as a sample, and forwarded to England.

"During the time that Captain Bennetts was employed in exploring this property he raised and forwarded to Quebec nearly twelve tons of ore, of an average yield of forty per cent. of copper, and a total value of about £500.

"With regard to the facilities for mining, it may be remarked that at Harvey's Hill the whole of the lodes may be cut by a level, at an average depth of about thirty fathoms.

"The land in this locality consists of about one-half cleared ground, available for the cultivation of corn and other produce, whilst the remainder is covered by an abundance of timber, well fitted for every mining purpose.

"The roads in the neighbourhood are all exceedingly bad, and must in some seasons be quite impassable; but the Grand Trunk Railroad passes within twenty miles of the mines, and considerable facilities exist for the construction of good common roads. The present cost of carrying ores from these mines to the St. Lawrence varies from £3 to £3 10s. per ton. Labour, and every manufactured material, is fifty per cent. dearer than in Cornwall. Water power, for the purpose of washing, is to be obtained on the mines.

"In conclusion, I would remark, that from the number of lodes already discovered, and the uniform success which has hitherto attended the shallow workings above described, there can be no doubt but that this ground forms a tract of more than ordinary promise, and one which merits a more extensive and systematic trial. I would add that a sum of from £5,000 to £6,000 will probably be found amply sufficient for opening out the mine. "J. Arthur Phillips."

"I beg to confirm the various statements made in the foregoing report, and to signify my concurrence with the opinions expressed by Mr. Phillips relative to the property of the Quebec & St. Francis Mining Company.

"Francis Bennetts, Jun."

"Kensington, February 11th, 1856."

The operations of the Quebec & St. Francis Company were sufficiently flattering to induce some gentlemen in London to organize in 1858 the English & Canadian Mining Company, with a capital of £40,000. The history of the English company was that of many another —each annual report regretted that operations were conducted at a loss, in spite of favourable developments and brighter prospects. Bad roads, costly transportation and insufficient water supply for ore dressing, were the really valid grounds for the disappointing results. The operations as gauged by shipments of a mine to-day, were contemptibly small. They were in—

The mining ton being 21 cwt., or 2,352 lbs.

But during the administration of the English company very interesting developments were made. In 1859-60 the value of the interstratified beds was first appreciated, and work was done on them. Mr. Williams, the superintendent, referring to the bed, reported to the Board on 4th February, 1860:

"I herewith beg to enclose you monthly report for January, in which I refer to the visit of our eminent Provincial Geologist, Sir W. E. Logan, to this place. He was much pleased with the works, and thinks we have a great future in our interstratified bed, and considers it a most valuable deposit; in fact, he did not expect to see anything so promising."

And on February 24th he reported:

"We have met with in our interstratified bed, within the last few days, a few isolated crystals of galena, which have given me an assay 72 1-2 per cent. of lead and 70 ounces of silver to the ton of lead. The quantity, however, that we have yet met with is so small as to be considered of no value, though I should be glad to see it increase and become one of our important products, which it might be, did we find it in a reasonable quantity."

The ore from the interstratified beds became henceforth the principal source of supply of the English company. Mr. S. Arthur Sewell, one of the directors, visited the mine, and he reported to the board that:

"This adventure must not be judged of by the rules applicable to those of like kind in this country. To estimate it properly we must take into consideration the almost primeval nature of the district, its distance from any rail or water communication, the scarcity and dearness of labour, the entire absence originally of all accommodation for residence at the mines, and its isolation from any markets where the necessaries of life or the appliances of civilization are procurable.

"With this in view, I must say that during my short stay at the mines I was astonished at the energy which, in a comparatively unsettled country, had pushed forward mining operations of great extent, over a surface of about fifty acres, had erected workshops, built cottages for the labourers, opened stores for their supply, dug reservoirs for water, made tramroads for the transmission of ore from the mines, and last, but not least, constructed roads through forests and over swamps for its further transmission to port for shipment."

By 1861 the directors issued a circular, in which they say:

"You are aware that the original capital of the company has been all called up. The returns during the present year have increased upon those of 1859, but are not sufficient to allow the payment of a dividend out of profit. The company's managing superintendent, Mr. Herbert Williams, is now in England. and will be at the meeting to explain the present condition and future prospects of the undertaking.

"The insufficiency of the present capital has been for some time manifest to the directors, and they have been in correspondence with Mr. Williams and the Canadian committee on the subject. Mr. Williams, in a letter dated the 10th October last, gives the following as his opinion of the sum required:

" 'In estimating the additional capital that we may probably require, the time occupied before we realize our products must be considered. It is twelve months since some of the ores now at Swansea left Harvey Hill, and the average, on account of our long winters, cannot be less than about nine months, unless we send some home by way of Portland, or try the Boston market during the winter months. Hence we shall require about nine months' working capital on the average of the year. Presuming we confine our expenditure to the present limited sum of £400 per month, we shall require a sum of £3,600 to carry on the work for that period. I fully trust we shall be able, before the expiration of the nine months, to open out sufficient grey ground to meet our expenditure by the products. Hence the following heads of expenditure will have to be considered by the board as the estimated capital required for completing the works already commenced, and, I trust, bring the mine, which certainly looks promising, into a healthy condition.

General exploration of the company's lands...	£2,000
Buildings	600
Roads	680
Continuation of Morrison's adit beyond the period of nine months	750
Working capital for nine months	3,600
Contingencies	370
	£8,000

"In consequence of the above communication your directors have made enquiries as to the best terms on which the above sum may be obtained, and have to report that a friend is willing to furnish the above amount, or such part of it as may be required, for three years, on debenture bonds, at 8 per cent. per annum, interest payable half-yearly, to be a first charge upon the property and produce of the mines, after paying working expenses."

But the report for 1862 opens with a cry of despair:

"At the formation of this company in the spring of 1858, it was little expected that four years would have elapsed without a sufficient return from Canada to divide as a dividend amongst the shareholders, but such is unfortunately the case up to this time, notwithstanding the indications of mineral wealth were and still continue to be of a very encouraging nature.

"The shareholders are aware that the capital of the company raised in England became exhausted in 1860, and that by resolutions passed at an extraordinary general meeting, held on the 28th February, 1861, power was given to the directors to raise on mortgage the sum of £8,000, to be taken up as the necessities of the company might require. The first installment of £1,000 was received from the late Mr. C. Tilt on May 1st last, and ,subsequently, four other sums of that amount have been received."

A fire at the ore dressing plant interfered with the shipments. The company sent out a Mr. Tregoning for advice. One of the paragraphs of his report expresses his bewilderment at the departure of our ore deposits from European standards.

"In these slates have been discovered some remarkable 'lenticular masses' and interstratified beds of copper ores, and these ores present with the slates in which they are embedded geological features totally different from those of the general mining districts of Northern Europe, but may be considered a type of an extensive cupriferous formation peculiar to this part of Lower Canada, and which there are strong reasons for believing contains a vast deposit of mineral wealth.

"From the appearance of the copper ores when discovered at the surface, they were supposed to be the 'out-crops' of what in depth would prove regular and well-defined lodes, as they did not coincide with the slates either in strike or dip, but after being opened, and yielding some considerable quantities of valuable (copper) ores, they were found to thin away from

their centres both horizontally and vertically, and disappear, having assumed the form of lenticular masses, variable in size, and succeeding each other at irregular intervals, and principally composed of quartz, associated with rich ores and bitter spar. In their occurrence and productiveness they will probably be governed by the bands of slates in which they are embedded. The probable average size of these lenticular masses is from 10 to 12 fathoms in length by 5 fathoms in height, and at the centre from 2 to 4 feet in thickness. Many far exceed these limits, and some are much less. They are equally variable in produce, as some have only yielded a few hundredweight of ore, while others have given several tons. About 300 tons of copper ores have been raised from workings made on these masses, worth about £6,000. Of this quantity about 60 tons, containing from 30 to 40 per cent. of copper, have been obtained from the Fanny Eliza alone, which has been discovered and worked at a depth of 30 fathoms from the surface, by cross-cut from Kent's shaft. This valuable discovery proves a singular and important feature of this enterprise, and one greatly in its favour, and from its appearance and the favourable geological character of the nacreous slates, there is every reason to believe that at greater depth these 'lenticular masses' will be found to increase in size and productiveness."

At this crisis some relief was received by a promise of a sale of the property to a Boston firm of brokers who advanced a forfeitable sum of $20,000. The value of the property was apparently assured by the concensus of so many notable experts, and the sale would probably have gone through but for the financial complications due to the increasing rise in the value of gold in the United States. These negotiations failing, the principal English shareholders tried in vain to float on the English market the London & Quebec Copper Mining Company, with a capital of £100,000. The Englishmen being unwilling to risk more in the venture, some Canadians undertook to pay the company's debts and to buy out the English shareholders.

The Canadian company never had adequate means for prosecuting the work. The old dressing floor had been planned after the oldest English models, using hand jigs and disregarding all labour-saving appliances. And the water supply was inadequate and variable, being derived from hillside reservoirs. When the English company was bought out, it was contemplated to build better works on the Palmer River, not more than a mile away; but this reasonable plan was abandoned in favour of the leaching method of Messrs. Whelply & Storer. It was a method based on sound chemical principles but carried out by the adoption of as many mechanical complications as perverse human ingenuity could devise to frustrate success. Pulverized charcoal was added to the ore to create an intense heat in a shaft furnace where a most moderate heat was required. Storing pulverized charcoal in a room lined with canton flannel is as dangerous as storing lighted matches, and the mill when it mysteriously caught fire exploded, rather than burned up, before the process had really had a fair trial.

The engine and boilers had been saved, and good concentrating works, provided with Rittenger jigs and designed on his general plans, replaced the Whelply & Storer leaching method.

After the fire in 1867 my father took a lease of the property, undertaking to pay $5,000 a year and to erect a 50-ton concentrating mill. His operations under the lease were less unsuccessful than they had been under the old company. The output rose to about 500 tons of concentrates a year, and the revenue nearly covered the actual operating expenses. It was, however, a struggle against penury; and while extravagance has wrecked many a mining enterprise, to the shifts and uneconomical expedients, incident to shortness of funds, not a few other failures have been due.

During this lease the bed which was supposed to run 3 1-2 per cent. carried that grade of copper over a comparatively limited area where a series of deep and surface veins affected its copper contents. Beyond this system of veins it carried apparently about 1 1-2 per cent. It could not, therefore, be worked profitably under the existing conditions with the existing appliances. But the deep veins, especially the Fanny Eliza, yielded an excellent grade of ore and promised so well that a Glasgow organization, the Harvey Hill Copper Company, subscribed a working capital in 1872. The Fanny Eliza Lode and the so-called East Lode had yielded the lessor most of his revenue, but were worked uneconomically by winzes sunk below the upper bed. Both veins looked so promising for permanency that Capt. Whitburn, who was sent out by the Glasgow company, decided to spend the company's working capital on a vertical shaft at nearly a couple of thousand feet distant on their strike from the point to which they had been explored. The veins were found where expected; but were barren and the company treasury was empty. The company was formally wound up in 1879. The same series of events have, I believe, been repeated since then—resuscitation, a lingering life, death and burial. And yet I think the property may deserve a better fate.

The ore deposits of Harvey Hill may well have puzzled Mr. Tregoning, as they have scant resemblance to those worked in Northern Europe; but in the rocks of the Quebec group and where those same rocks occur in North Carolina and elsewhere, they sometimes carry copper under similar conditions.

At Harvey Hill three beds were met with which, if they extend over the entire hill, would exist at the following depths below the surface at Kent's shaft:

1. The uppermost bed, cut in grass-shaft No. 2, and from which a great deal of ore has been extracted by the Kent shaft, at 20 fathoms from the surface.
2. The second bed, that lying on the soapstone in Fremont's shaft, which should be at about 60 fathoms from the surface; and
3. The lowermost bed, that met with near the end of the adit, and which should be at about 20 fathoms deeper still, or at 80 fathoms from the surface.

There is, however, no likelihood of these beds being of such great extent, and it is certain they are not of the uniform richness at one time attributed to them.

No exploratory work was done, and no ore was extracted from any of the beds but the uppermost, and as the deeper beds were not encountered in sinking on the shoots of ore in the Fanny Eliza vein, they probably are not of very great extent. The areas of these beds and their copper contents could, however. be very cheaply determined by either churn or diamond drills.

Should any intention to re-open the mines be seriously contemplated, such preliminary exploration work should be done on the beds, as the contribution of ore from the veins, though valuable, would probably be small and the beds would have to be looked to for quantity. The opinion expressed by the Geological Survery that the beds fed the veins is questionable. The impression made on me was rather that the deeper veins fed the upper bed, as its slates were most productive where the deeper veins entered it. These apparently not only enriched it but injected into its slates the con-

stituents which composed their gangue. On the Harris lot, one mile from Harvey Hill, a shallow shaft was sunk on a vein of bitter spar yielding copper glance and visible gold; but neither here nor on any part of the property was what would be considered thorough and judicious development work ever done. Company after company undertook to work the mines with insufficient capital. The cost of mining and concentrating, as compared with modern methods of stoping, on a bed ten feet in thickness, were high.

They used to be estimated at:

Mining, per ton	$4.00
Dressing the ore (concentrating), per ton	1.75

The cost of transportation to Quebec was $10.00 a ton, and to Boston, $15.00 a ton. Harvey Hill may now be considered to be on the Quebec Central Railway. The above figures for extraction and treatment might now be reduced to one-third.

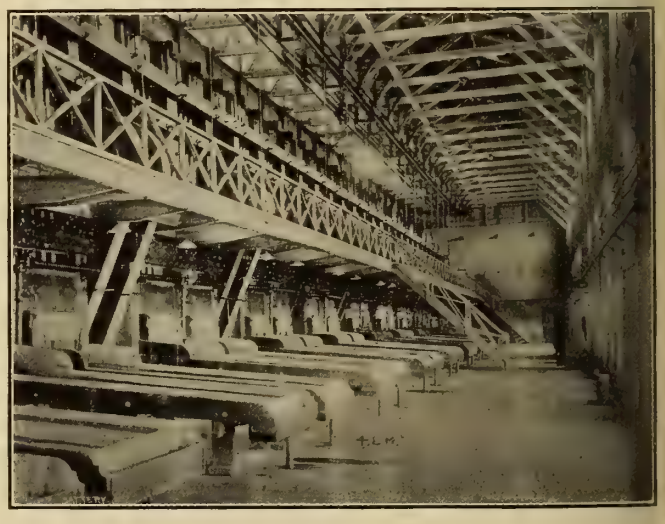
But it is doubtful whether any of the mines of the province would be singly productive enough to feed a profitable smelter, and few copper ores or even copper concentrates can bear a heavy transportation charge. If the copper mines of the province are to be advantageously opened, it should be on some principle of co-operation by a strong company.

These copper deposits were, when they were most actively worked, distributed as occurring in "three synclinal troughs."*

The first is briefly defined as "the synclinal extending from the Township of Farnham, near Missisquoi Bay, to the Seigniory of Lauzon, on the St. Lawrence. This, where it is traversed by the St. Francis, is nearly or quite separated into two parts by the appearance of the underlying slates. The southwestern portion appears to be divided by an undulation into at least two subordinate troughs, thus giving the Roxton and Ely an additional breadth to the exposure of these rocks. The copper deposits of Upton, Acton, Wickham, Roxton, and Durham, occur in this synclinal, while in its northeastern extension are those of Wendover, Somerset, Nelson and St. Flavien."

The second synclinal is described as "extending from St. Armand to the Seigniory of St. Mary, on the Chaudiere. In it are the copper deposits of Sutton, Shefford, Stukely, Melbourne, Cleveland, Shipton, Chester, Halifax, Leeds, Inverness, and St. Mary. In its southern extremity, this synclinal is divided into two by Sutton Mountain, and while one part occupies Sutton Valley, the other extends southward into Potton . . ."

The third synclinal is described as "extending from the Owl's Head Mountain on Lake Memphremagog, to Ham, and includes the Stoke Mountains. An extension of this is traced north-eastward to Vaudreuil and St. Joseph, on the Chaudiere and beyond it, into Buckland. Between the southwestern portion of this synclinal and the second one, is a large area occupied by newer rocks, of the same age as those which limit the belt to the southeast. They include the slates and limestones which occupy the northern part of Lake Memphremagog; and, extending through parts of Oxford, and Brompton, cover a considerable area in the contiguous parts of the Townships of Windsor, Wotton, Ham and Stoke. These unconformable rocks overlie and conceal a large portion of the strata of the third synclinal; but along the eastern limit of this are exposed the copper deposits of Ascot, Ham, and Garthby."



* The Geological Survey Report for 1863, page 709.

Roughly speaking these three groups of deposits, some of which may be developed into mines, contain the necessary elements of a favourable smelting mixture. In the first group are the calcarious ores of Upton and Acton. In the second the silicious and aluminous ores in the slates of the Quebec group. The leanest are suitable for concentration to a higher grade. The richer would bear transportation to a central smelter. In addition to the ores of Harvey Hill, others of the group worthy of examination are the mines still owned by the Megantic Mining Company, in Inverness, New Ireland, and Halifax; and also the Viger Mine and other mines in Chester and St. Armand counties. The third group would yield the essential element of sulphur, without which economical smelting could not be conducted. Such a scheme would, of course, require much preliminary study, prudent development work, and then abundant capital for its realization, should the study and development work justify this third step. Singly, the deposits are probably too small to be self-supporting, and their ores are unfit for isolated treatment, whereas consolidated there may be the material for a successful enterprise.

AN ENGLISH GOLD STAMP BATTERY IN SOUTH AFRICA.

By Frank C. Perkins.

The accompanying illustration shows the arrangement of a 120-stamp mill sent out to South Africa by the Sandycroft Foundry Company, Limited, of Chester, England, having stamps of a falling weight of 1,250 pounds. This gold stamp battery is in operation at Johannesburg in South Africa and is constructed on the high bank principal. It is stated that this type of mill is the one most in use at the present time in South Africa, and, it is maintained, possesses many advantages over other forms in operation in that country.

Large numbers of grinding pans are utilized as constructed in this English works, instead of using tube mills. These grinding pans for regrinding after milling are said to cost considerably less than tube mills and are held to be equally effective. Whether these grinding pans will ever supersede tube mills is questioned by many mining engineers, but in the meantime their operation is being watched with interest.

MINERAL PRODUCTION OF BRITISH COLUMBIA IN 1909.

Annual Report of the Minister of Mines.

The annual report of the Minister of Mines for the year ended December 31, 1909, being an account of mining operations for metalliferous minerals, coal, etc., in the Province of British Columbia, has been issued. Some of the statistical tables give the total mineral output of the province to the end of 1909, while others show in considerable detail the actual mineral production of last year, based on smelter and mill returns. Comparative tables exhibit the production of separate minerals during four years, 1906-1909, thus illustrating by comparison the progress made in productive mining in that period.

Table I. shows the total gross value of each of the chief mineral products mined up to the close of 1909. From this it will be seen that of the aggregate of $347,820,584, coal mining has produced the highest individual total amount, $102,904,261; next in importance is placer gold, with a total of $70,673,103, and then copper at $55,871,893. If placer and lode gold be taken together, a total of $125,950,790 is obtained, thus placing this mineral at the head of the list in regard to total value of production. The figures for the several minerals appear below:

TABLE I.—Total Mineral Production for all Years to 1909, Inclusive.

Gold, placer	$ 70,673,103
Gold, lode	55,277,687
Total gold	$125,950,790
Silver	29,850,586
Lead	23,259,255
Copper	55,871,893
Other metals	890,699
Total metals	$235,823,223
Coal and coke	102,904,261
Building stone, bricks, etc.	9,093,100
Aggregate value of production	$347,820,584

Table II. shows the value of the mineral production of the province for each individual year from 1890 to 1909, both years inclusive, during which period the value increased nearly ten-fold. Table III. presents in graphic form the facts shown in figures in the tables, and demonstrates, to the eye, the rapid growth of lode mining, also the fluctuations to which it has been subjected.

Table IV. gives a statement in detail of the quantities and value of the different mineral products for the years 1907,1908, and 1909. This table follows:

TABLE IV.—Quantities and Value of Mineral Products for 1907, 1908, and 1909.

	Customary Measure.	1907 Quantity.	1907 Value.	1908 Quantity.	1908 Value.	1909 Quantity.	1909 Value.
Gold, placer	Ounces	41,400	$ 828,000	.....	$ 647,000	.....	$ 477,000
Gold, lode	Ounces	196,179	4,055,020	225,582	5,282,880	238,224	4,924,090
Total gold		.....	$4,883,020		$5,929,880		$5,401,090
Silver	Ounces	2,745,448	1,703,825	2,631,389	1,321,483	2,532,742	1,239,270
Lead	Pounds	47,738,703	2,291,458	43,195,733	1,632,799	44,396,346	1,709,259
Copper	Pounds	40,832,720	7,166,544	47,274,614	6,240,249	45,597,245	5,918,522
Zinc		.....	.....	.....	270,000	.....	400,000
Total metallic		.....	$17,044,847		$15,394,411		$14,668,141
Coal	Tons, 2,240 lb.	1,800,067	6,300,235	1,677,849	5,872,472	2,006,476	7,022,666
Coke	Tons, 2,240 lb.	222,913	1,337,478	247,399	1,484,394	258,703	1,552,218
Building materials, etc		.....	1,200,000	.....	1,100,000	.....	1,200,000
Total value of production		.....	$25,882,560		$23,851,277		$24,443,025

Table V. shows the respective proportions of the mineral production made in each of the districts into which the province is officially divided. It will be observed that Yale (Boundary) district continues to hold the honour of first place on the list. The Coast district, which in 1908 was third, last year changed places with West Kootenay, and came second. East Kootenay was again fourth. The Coast and East Kootenay districts obtain a considerable proportion of their output from coal mines situated within their respective limits, whereas in the other districts the production is almost entirely from metal mining.

TABLE V.—Production of Mineral by Districts and Divisions.

Names.	Divisions. 1907	Divisions. 1908	Divisions. 1909	Districts. 1907	Districts. 1908	Districts. 1909
Cariboo District	.....	.....	.....	$ 360,500	$ 405,000	$ 247,000
Cariboo Mining Division	$ 306,500	$ 355,000	$ 220,000	.....	.....	.....

Other tables, not here reproduced, are as follows:

No. VI. gives the statistical record of the placer-gold mines of the province from 1858 to 1909, inclusive, and shows a total production of $70,673,103. The output for 1909 was less than that for 1908 by about 26.2 per cent.

No. VII. relates entirely to the lode mines and shows the quantities and value, respectively, of the various metals produced each year since the beginning, in 1887, of lode mining in the province. The gross value of the products of these mines (excepting zinc, which is not included in this table), is $164,259,421. The value of the production of lode minerals in 1909 was rather less than in 1908.

No. VIII. contains the statistics of the production of the coal mines of British Columbia. The total quantity of coal mined to the end of 1909 was 29,629,025 tons (of 2,240 pounds), valued at $92,010,796. In these figures the quantity of coal used in the manufacture of coke is not included. The production of coal was commenced in 1895; the total quantity made to the end of 1909 was 2,032,890 long tons, valued at $10,893,465. The average selling prices used in calculating the value of the coal and coke production prior to 1907 were $3 per long ton of coal and $5 per ton of coke. For the last three years the prices used have been $3.50 for coal and $6 for coke.

No. IX. exhibits details of production of the mines of the province (excepting the coal mines) for four years, 1906-1909, and the districts in which such production was made. The tonnage of ore mined in each district, with its metallic contents and market value, is shown. The total tonnage of ore mined in 1909 was 2,057,713 tons, having a gross value, including building materials, of $15,868,141. This compares with 2,083,606 tons, valued at $16,494,411 in 1908. The percentage of tonnage and value derived from the various districts of the province last year were as under:

	Tonnage, p.c.	Value, p.c.
Yale (Boundary) district	71.03	53.92
Trail Creek mining division	11.55	20.84
Fort Steele mining division	7.28	9.65
Slocan district	1.37	4.02
Coast district	1.92	2.18
Other parts of province	6.85	9.39
	100.00	100.00

No. X. compares graphically the output of mineral products of British Columbia with that of similar products in all the other provinces of the Dominion, and shows that in 1909 this province produced in the minerals shown an amount equal to about 67.8 per cent. of that of all the other provinces of Canada combined.

Progress of Mining.

From the comments of the Provincial Mineralogist on the Progress of Mining the following information has been taken:

While the value of the mineral production of the province in 1909 was less than in the years 1906 and 1907, it was considerably greater than that of any earlier year than those.

The tonnage of ore mined, exclusive of coal, was 2,057,713 tons, which quantity was a decrease as compared with the tonnage for 1908 of 25,893 tons, or 1.24 per cent. This tonnage was produced by the various districts in the proportions shown by the next following figures: Yale district, Boundary mines, 71.03 per cent.; West Kootenay district, Rossland mines, 11.55 per cent.; East Kootenay district, mines in Fort Steele division (chiefly the St. Eugene), 7.28 per cent.; Coast district, 1.92 per cent.; all other parts, 8.22 per cent.

The number of mines from which shipments of ore were made was 89, and of these only 52 shipped more than 100 tons each during the year, while but 32 shipped in excess of 1,000 tons each. Of the latter, 8 were in Nelson mining division, 5 in the Boundary, 5 in Ainsworth division, 4 in Slocan district, 3 in the Coast district, 3 in Trail Creek (Rossland) division, 2 in Fort Steele division, and one each in Trout Lake and Queen Charlotte divisions.

The number of men employed were: In metalliferous producing mines, 3,037 (2,048 below and 989 above ground); in mines not shipping ore, 217 (136 below and 81 above ground); total, 3254. A mine employing say 12 men for four months was credited with four men for 12 months, so that the total above given is less than the actual number of men who worked in the mines during the year. The number employed at the coal mines was 6,418, this including 215 white boys, and 672 Chinese, Japanese, and Indians. The official figures of all employed at the mines of the province therefore give a grand total of 9,672. Although it is not so stated in the report, it is quite probable the 1,000 or more men employed at the several smelting works are not included.

Coal.

The coal produced was mined chiefly by three companies, namely, the Wellington Colliery Company and the Western Fuel Company, on Vancouver Island, and the Crow's Nest Pass Coal Company, in southeast Kootenay; these companies together produced about 88 per cent. of the total coal mined. Of the smaller collieries, those on Vancouver Island were the Pacific Coast Coal Mines, Limited, with about 70,000 tons, and the Vancouver-Nanaimo, with 10,000 tons; in the Nicola district, the Nicola Valley Coal & Coke Company's production was about 62,000 tons, and the Diamond Vale Company's about 1,700 tons; in the Crow's Nest district, the

Hosmer and Corbin collieries each produced about 60,000 tons. The gross output of coal was 2,400,600 tons of 2,240 pounds), of which 998,494 tons was sold for consumption in Canada; 741,646 tons exported, mostly to the United States; 260,554 tons burned under colliery boilers, etc.; 394,124 tons used in making coke, and 5,782 tons added to stock. The quantity of coke made was 258,703 long tons, of which 210,884 tons was sold for use in Canada; 40,629 tons exported, nearly all to the United States, and 7,199 tons added to stock. The production of coal was the largest for any year since coal mining was commenced in the province; that of coke was second only to that of 1905, when 271,785 long tons was made.

Gold.

The production of placer gold was $477,000, as against $647,000 in 1908, and this was the smallest amount produced in any year since 1894. The decrease in output was attributable partly to the short water supply last season.

The value of lode gold was $4,924,090, a decrease of $358,790 as compared with 1908. Nelson, Boundary, and Coast districts each produced more lode gold, but the decrease in Rossland camp was larger than the total of the increases in other parts of the province. About 86.5 per cent. of the lode gold was recovered from smelting ores also copper-bearing; the remaining 13.5 per cent. was from ores treated in stamp mills, etc. The larger stamp mills operated last year were those of the Hedley Gold Mining Company at Hedley, Similkameen, with 40 stamps; Granite-Poorman mill, near Nelson, 20 stamps, and Queen mill, Sheep Creek, 20 stamps. There are two small mills at Sheep Creek mines, one of which, at the Nugget mine, with four stamps, was worked nearly all the year.

Silver.

The silver produced totalled 2,532,742 ounces, a decrease in quantity of 98,647 ounces and in value of $82,213, as compared with 1908. About 98.2 per cent. of this was from silver-lead ores and the remainder from copper-silver ores. The Slocan district—including Ainsworth, Slocan, Slocan City, and Trout Lake divisions—produced about 50 per cent. of the total, and Fort Steele division of East Kootenay 23 per cent., all from argentiferous galena ores.

Lead.

Lead showed a production of 44,396,346 pounds, this being an increase of 1,200,613 pounds in quantity and $76,460 in value over that of 1908. Mines in Fort Steele division (chiefly the St. Eugene), produced nearly 61 per cent. of this total; those in Ainsworth and Slocan, 34 per cent., and in Nelson and Trout Lake divisions, 5 per cent.

Copper.

The amount of copper, placed at 45,597,245 pounds, was less in quantity by 1,677,369 pounds, and value by $321,727 than in 1908. These figures do not take into account smelter charges or deductions, but show the copper contained in the ore smelted. There was a slight increase in the Boundary district and Nelson division, but a heavy falling off in Rossland camp and the Coast district. The proportions of production of districts were: Boundary, 89.04 per cent.; Rossland, 7.70 per cent.; Coast, 2.84 per cent., and Nelson, 0.42 per cent. The average assays of copper in ores of the several districts, based upon copper recovered, were: Boundary, 1.41 per cent.; Coast, 1.5 per cent.; Rossland, 0.75 per cent.

Iron and Zinc.

No iron ore was shipped and very little mined, there having been no market in 1909 for iron ore from the province.

About 10,000 tons of zinc ore and concentrates was sold in 1909, the zinc contents ranging from 38 to 42 per cent. The Lucky Jim, Slocan, was the only mine that shipped zinc ore; it sent out 4,700 tons averaging 48 per cent. zinc. The Whitewater group, Ainsworth division, produced 4,600 tons of zinc concentrates, containing 38 to 43 per cent. zinc, also silver from 15 to 25 ounces per ton. Mills of other mines produced zinc concentrates of similar value, but little of their production was sold.

Building Materials, Etc.

Of building materials, etc., the chief production was in granite and sandstone, bricks, pottery, lime, and portland cement. Much building stone was supplied to Coast cities, in which many substantial buildings were erected. Three marble quarries, one on Vancouver Island and two near Kootenay Lake, were worked, and one of the latter sent out about $30,000 worth of marble, largely to prairie cities. The estimated production of red bricks was 40,000,000. Some excellent fire bricks and fancy building bricks were also manufactured. Pottery products were estimated at $100,000. Portland cement was made near Victoria, Vancouver Island; some 238,000 barrels was the output, valued at $360,000.

Features of the Report.

Prominent features of the report, other than the statistical tables and accompanying comments of the Provincial Mineralogist (Mr. Wm. Fleet Robertson) on the progress of the year, are accounts of visits paid by that official to several mining districts, and his observations on matters and things that came under his personal notice. Among the districts he visited were the Queen Charlotte Islands; the partly developed and producing coal mining district in the Crow's Nest Pass country, and the important though undeveloped coal areas in the upper Elk River district, computed by Mr. D. B. Dowling, of the Dominion Geological Survey, to embrace 140 square miles of coal-bearing country, with a probable workable coal content of 100,000,000 tons per square mile; the metalliferous mineral region in East Kootenay lying between Golden and Field, on the Canadian Pacific main line railway, and the vicinity of Moyie Lake, on the Crow's Nest Railway, on the south; the Duncan River district, in Ainsworth division, and Sheep Creek camp, in Nelson division. Much information is given concerning these several regions, of parts of which there was not on record any official information obtained in recent years. The illustrations of places and scenes in some of these little-known parts add to the value of the report.

Several official reports on the disastrous explosion that took place at the Wellington Colliery Company's Extension colliery, Vancouver Island, last October, when 32 men lost their lives, are printed; with these are diagrams and other illustrations of especial interest to men connected with coal mining.

The bulletin by Mr. Herbert Carmichael, Provincial Assayer, issued by the Bureau of Mines last winter, is reprinted in the annual report. At this time, when Portland Canal district, which it describes in some detail, is attracting much attention, this will be of particular value.

As is usual with the British Columbia Government printing office, the printing of the report, and the finish

of the half-tone illustrations, are very creditable. The reproductions of photographs are superior, and beside these decidedly ornamental illustrations, there are graphic tables, diagrams, maps, etc., to also add to the usefulness of the report. It is to be regretted that it was not practicable to get it ready for issue earlier in the year, but, though late, it will be found of much value throughout the wide field over which it will be distributed.

MINE-RESCUE STATIONS IN BRITISH COLUMBIA

With a view to the early establishment of mine-rescue stations in British Columbia, as required by the "Coal Mines Regulation Act" in force in that province, the Provincial Government has ordered Draeger oxygen breathing helmets and all requisite accessories for the full equipment of three mine-rescue stations, one of which will be established at Hosmer, Crow's Nest Pass district, which is about the most central place that could be chosen in that important coal field, and two on Vancouver Island—one at Cumberland, where is situated the most northerly of the big collieries in operation on the Island, and the other at Extension, where there was a serious and fatal disaster last October. As railway connections exist between Hosmer, and Michel and Corbin in one direction, and Hosmer, and Coal Creek and Carbonado in another, the advantage of that point for one of the Government stations is apparent. Similarly, there are railway connections between Extension, and South Wellington and Nanaimo, on Vancouver Island, so here again it is manifest that the officials of the Provincial Bureau of Mines have been giving the subject of advantageous situation of the stations their careful attention. It is planned to fit up railway cars, where practicable, as storage rooms for the Draeger apparatus, so that on emergency there will be a minimum of delay in the transportation of apparatus and those trained in its use to the scene of operations wherever their services shall be required.

Last March the Legislative Assembly of British Columbia amended the "Coal Mines Regulation Act," an important addition to which was the following section:

"82a. There shall be established by the owner, agent, or manager of every colliery to which this Act applies such number of oxygen helmets, or some such form of mine-rescue device as may be approved by the Minister of Mines.

"Such mine-rescue apparatus shall be constantly maintained in an efficient and workable condition, and shall in all cases be so stored, or placed about the mine, as to be always available for immediate use.

"The Lieutenant-Governor in Council may, from time to time, establish mine-rescue stations for the purpose of supplementing, in case of need, the colliery installations of mine-rescue apparatus, and also for the purpose of training the holders of Certificates of Competency under this Act in the use of such mine-rescue device as may be approved by the Minister of Mines; and it shall be incumbent on the owner, agent, or manager of every operating mine to which this Act applies to retain such number of employees trained in the use of such established mine-rescue apparatus as the Chief Inspector of Mines may deem sufficient:

"Provided that in cases of emergency such stations shall be available for the use of any trained corps of mine-rescuers, duly qualified medical practitioners, or corps trained in the work of first aid to the injured.

"This section shall come into force upon proclamation by the Lieutenant-Governor in Council."

Circumstances have since been such that the Lieutenant-Governor in Council has not yet issued the proclamation requisite to bring this section into force, but meanwhile much active interest has been taken in the subject of mine-rescue by the Provincial Department of Mines. The Deputy Minister (Mr. R. E. Tolmie), Provincial Mineralogist (Mr. Wm. Fleet Robertson), and Chief Inspector of Mines (Mr. F. H. Shepherd) have visited Seattle, Washington, on different occasions, to see the work being done at the United States Geological Survey mine-rescue training station there in conjunction with the Washington State authorities and the University of Washington. Information concerning this training station was printed in the Canadian Mining Journal of June 1 (pp. 334-5). There is little doubt the proclamation provided for in the last clause above quoted will shortly be gazetted, and by that time the Provincial Government will probably have received the apparatus it has ordered and have established its mine-rescue stations.

It is significant that the only company operating in the province that has anticipated the coming into law of the provisions requiring that mine-rescue apparatus be obtained and be available for immediate use, is the Western Fuel Company, the chief shareholders in which (if not all of them) are residents in the United States. The Canadian companies appear to be waiting until the law compels them to make this provision for mine-rescue, and perhaps life-saving, purposes.

Last February the Western Branch of the Canadian Mining Institute passed a resolution favouring the remission by the Federal Government of customs duty on mine-rescue apparatus, and this resolution was forwarded to Hon. Wm. Templeman, Minister of Mines. It would be interesting to hear that Minister explain to the coal miners of Canada what he has since done towards facilitating in this way the provision of life-saving apparatus, in which they are so vitally interested.

CANADIAN MINING INSTITUTE.

Proposal to Reprint Vols. I. to V. of the Journal.

Volumes I. to V. (inclusive) of the Journal of the Canadian Mining Institute being out of print, the Council contemplate publishing a revised edition of the five volumes in question provided a sufficient number of subscriptions thereto are received. It is proposed to reprint the five volumes in question in two volumes, the first to include Vols. I., II. and III. of the Journal, and the second, Vols. IV. and V. Each volume will comprise about five hundred pages.

The subscription price based on the actual cost of the undertaking has been placed at twelve dollars.

The oil companies that control the great Baku district of southern Russia are substituting electric power for steam.

Great Britain produces 1,900,000 tons of salt a year; all Europe less than 5,000,000.

HAMMER DRILLS IN OVERHAND STOPING AND RAISING.

By H. B. Williams, Associate.

Paper read before the Institution of Mining and Metallurgy.

The numerous advantages obtained by the recent substitution of hammer drills in place of hand labour and ordinary piston drills having now been sufficiently demonstrated by means of exhaustive trials and practical operation in stoping and raising at the Granite Gold Mines, British Columbia, I herewith append an account of my experience of their performance.

Overhand or back-stoping only is practised at these mines, the reef consisting of hard quartz from 8 in. to 5 ft. in width, containing 2 per cent. to 10 per cent. of sulphides of iron and arsenic, while the country rock is a dark closegrained granite. The vein underlies at angles varying from 35 per cent. to 50 per cent.

Figures being available to show the cost of stoping as practised in previous years at the mines, this paper is written with the object of a general comparison of results by the various methods employed, and in particular with regard to those obtained with the hammer drill. The drill found most efficient is the Waugh stoping hammer drill, a 2-in. cylinder, valve machine. The principal wearing parts are the piston hammer, costing $4.00, the chuck $3.50, tappet $2.00, and complete valves $10.00.

A general description of the mechanism of the machine in question is as follows:

Referring to Figure 1, the drill is 4 ft. in length, weighing 60 lbs., its greatest diam. being at the barrel A, 3¼ in. The cylinder is 2 in. in diam., while the automatic telescope air pressure feed (B) allows of an extension of 24 in. The hammer (C) is a piston the blow of which is regulated by a valve (D); the hammer strikes a tappet (E), the latter in turn delivering the percussion to the end of the shank of the drill steel, which is held in alignment with the drill in a chuck (F) of hardened steel. Rotation of the machine and consequently of the drill steel is effected by the hand lever (G). With an air pressure of 60 lbs, 1,000 blows per minute are struck by the hammer, its stroke being 2½ in.

In operation underground, a starter having been placed in the chuck, and the hose coupled to its connection, the hammer drill which, as previously stated, is designed for the boring of uppers in overhand stoping and raising only, is set up with the extension end on a rough sollar (Fig. 2). This sollar may be laid on broken ore or across the stope timbers at a convenient distance from the face of the stope, and the machine is so aligned as to take the best advantage of the heads occurring in the ground to be broken.

Air now being turned on, the extension piston automatically brings the bit of the drill steel forward into contact with the rock, percussion of the drill steel by the tappet commences, and the rotating lever being operated by the machine man, pitching and subsequently drilling of the hole proceeds to the depth required.

Holes up to 4 ft. in depth are bored by these machines. The drill steel used is of light cruciform section in lengths of 18, 27, 36, 45, and 54 inches, allowing 9 in. changes for each bit. It has been found important to forge and harden the drill shanks with care, 1 in. square, where they fit in the chuck, as it is at the chuck that most wear and tear occurs with these machines.

It has been suggested to myself that with slight wear only of the chuck and of the shank of the drill steel, the alignment of the machine itself and the drill steel would not coincide, and in consequence there would be a tendency to "fichured" holes; experience at the Granite Mine has proved to me that the number of fichured

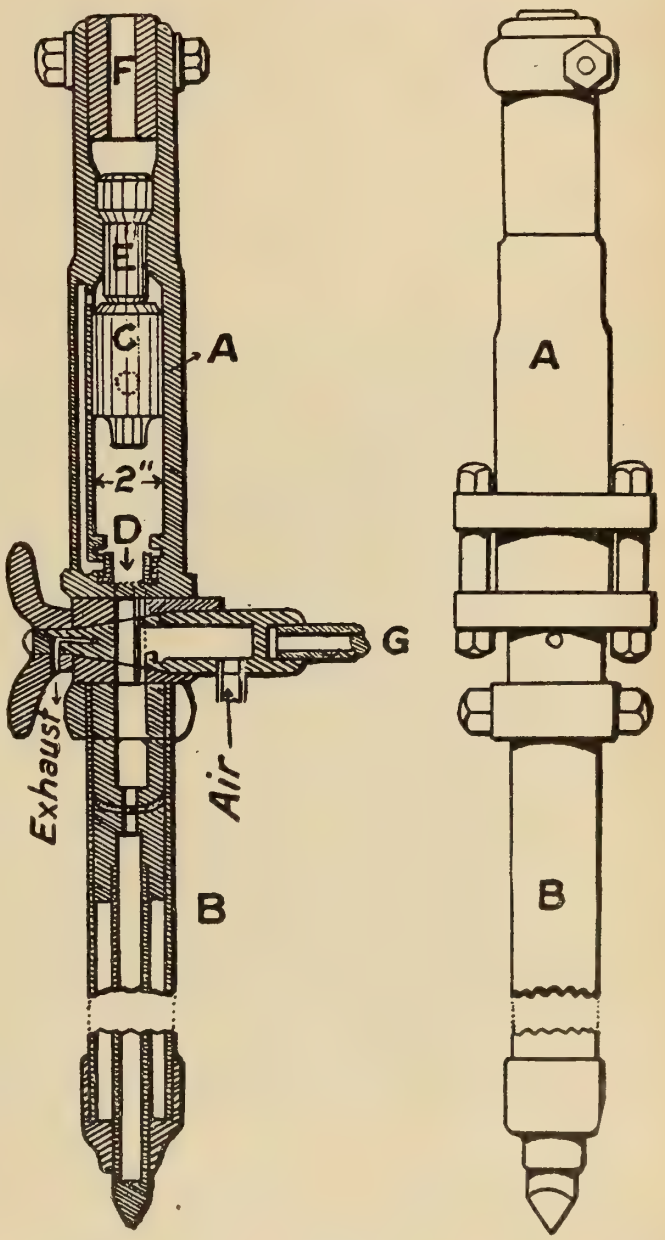

Fig. 1.

holes is small though the ground is "heady"; difficulty is experienced only when the drill bores into soft gouge which occasionally occurs on the hanging wall.

It has been found more satisfactory to avoid the boring of holes at an angle of less than 35 degrees from the horizontal. At smaller angles the dust does not clear

from the holes by gravity, and owing to the unsupported length of the machine and drill steel the leverage is sufficient to cause the drill steel to break, usually close to the chuck, and to wear the hole in the chuck itself unduly; considerable additional friction and consequent loss of boring efficiency is also caused by the boring of flat holes. With a reef underlying at over 35 degrees, as is the case with the Granite Mines, there is only occasional necessity for a low-pitched hole.

Machine men running the hammer-drills are instructed to attend carefully to the lubrication of their machines, which is essential owing to the somewhat delicate

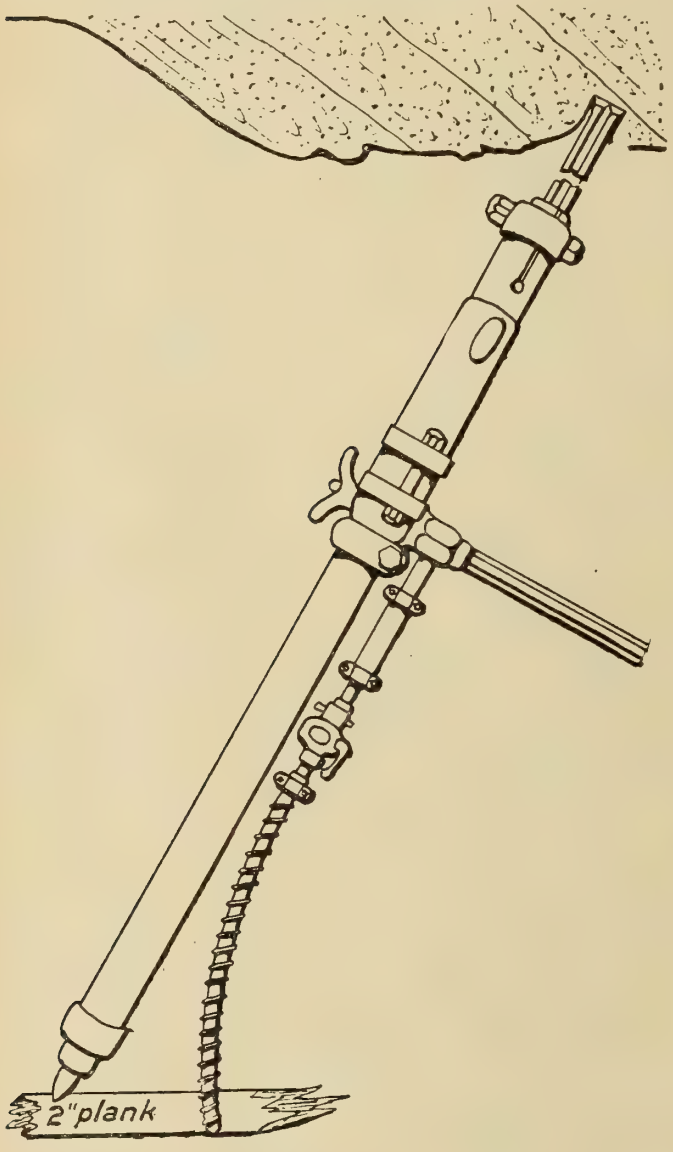

Fig. 2

mechanism of the valves. Recently an automatic lubricator has been supplied combined with the air-connecting plug, which now ensures constant oiling of the machine for a full shift without replenishing the oil-chamber.

I now propose to deal with the advantages of the hammer drill over piston drills manifested in the tests underground, which led to the final adoption of the former at the mine for stoping and raising.

The lightness and general handiness of the 2-in. hammer drill, its weight being only 60 lbs., against the 125 lbs. of the 2-in. piston stoping drill, is a point in its favour.

There is a considerable saving of time in setting up. In a shift of eight hours, it can be safely estimated that the loss of boring time in setting up, changing steel, and taking down a piston drill is two hours; with the hammer drills half-an-hour only per shift is sufficient, less time is lost in changing steel, there being no U-bolts, bars, or mountings to manipulate.

Inexperienced hand-labour miners can learn to run the hammer drills in a few shifts, a great advantage in a country where good machine men are difficult to procure.

Greater drilling efficiency has been obtained. With the small 2-in. one-man piston drill, a shift's work comprising a total footage bored of between 25 and 30 ft. was considered satisfactory, whereas the hammer drills bore ten 4-ft. holes, or an aggregate of 40 feet per shift. The bitts of the drill steel are not dulled by the quick, light blows of the hammer drill to the extent which occurs with the heavier blows from the piston drill.

Owing to the fact that the hammer drill is so compact and requires no bar or mountings, holes may be bored to take the greatest advantage of slips in the ground in low stopes, and greater efficiency in breaking ground has resulted.

The construction of the hammer drill renders its adaptability most evident for carrying considerably lower stopes than with the piston drill, a great saving of cost in stoping narrow reefs, such as those of the Granite Mines.

I have been struck with the small quantity of fine dust made by the hammer drill in the stopes and rises. I account for this improvement over piston drills by the fact that there is no churning movement of the drill steel in the hole, as is the case with the piston drills, the bitt of the drill steel held continually in the bottom of the hole while boring. The air is exhausted back from the face of the stope and no air can escape at the chuck end of the machine. It may also be noticed that the hammer drills possess the advantage of producing coarser cuttings than the piston drill.

In air consumption I have found that with a receiver pressure of 80 lbs., there is only a slight advantage in practice in favour of the 2-in. hammer drill over the 2-in. piston drill.

Having related the advantages of the hammer drill over the piston drill, as proved by their successful operation for some months past at the Granite Mines, I now propose to deal with the reduction of costs in stoping effected by their use.

A comparative statement of stoping costs under various methods is as follows:

Stoping by hand labour	$3.50 per ton.
Stoping by 3¼ in. rock drill (piston)....	2.90 per ton.
Stoping by 2¼ in. rock drill (piston)....	2.08 per ton.
Stoping by 2 in .hammer drill	1.53 per ton.

In the above statement no allowance is included for development charges, compressed air, or depreciation of plant generally. In reference to this point, however, it may be of interest to mention that the total costs, including all charges of mining transportation, milling and realization, etc., at the Granite Mines, have recently been reduced from $5.32 to $3.25 per ton, although the high cost of labour and supplies locally shows no diminution, a result mainly attributable to the adoption of the hammer drills.

It must be borne in mind, in considering the value of the above figures in comparison with larger mines' costs,

that they refer to a mine equipped with a plant capable of crushing 1,500 tons per month only, and that the greater proportion of the stopes worked recently carry a reef with an average width of only 15 inches.

On account of the simplicity and small number of moving parts, the repairs and general upkeep of the hammer drills work out at approximately only $5.00 per month, which compares favourably with these charges in the case of the piston drills. Owing to its compact tube-like design, the hammer drill withstands the invariably rough handling without the breakages so common with piston drills.

The advantages in general handiness, increase in progress and consequent reduction of cost in raising with the hammer drill are even more marked than in the case of stoping by its use.

CANADIAN MINERALS AT THE BRUSSELS EXHIBITION.

(Written specially for the Canadian Mining Journal.)

In view of the fact that Canada made such a large display of minerals at the Liege Exhibition, in 1905, it is worthy to note the increased and intelligent interest this branch of our natural resources is arousing at the present exhibition.

Much wonder is expressed at the rapid development of the Dominion, the variety of its minerals and the vast extent of territory that is open to the prospector. But many predictions of the extent to which the mineral industry will be carried, seem overdrawn.

Those who have worked in Belgium and other countries with the knowledge of what has been done under most unfavourable conditions grant to Canada greater possibilities than even we ourselves appreciate.

Canada's undeveloped water powers, coupled with the immense coal areas, represent to them an asset of reserved energy that will be the greatest factor of development in the years to come. To enter into details of the installation of the mineral exhibit would require much time and space. All the principal mining interests are fully represented. As an educational section this one is not equalled in the entire exhibition. Through the great coal measures of Nova Scotia we pass to New Brunswick, with its shales and large gypsum deposits, then to Quebec rich in asbestos and other minerals; Ontario, with its silver and nickel mines unequalled in the world; Manitoba and Saskatchewan, with structural materials and natural gas proven at a few points; Alberta, rich in coal, anthracite and bituminous. British Columbia's large areas of coal on the coast and in the interior valleys, with the rich deposits of gold, silver, lead and copper ores throughout the province, give it prominence over the others. The interested visitor, after following the mineral occurrences as arranged, looking at the map of the Dominion, sees that only about one-half of the rim has been touched. During my visit to Brussels I came in touch with a number of persons interested in the development of some of the Canadian properties; they spoke in high terms of the exhibit in the Canadian section, and of the good work the government was doing through this medium.

So long as your government can come to us, as in the case of Liege, 1905; Brussels, 1910, and show that the statements made have been carried into actual fact ,we will be mutually benefitted. In 1904, your mineral production was a little over $60,000,000.00, of which you were proud. For last year you show an output of over $90,000,000.00. These are the facts that impress us most.

Since 1905 much Belgian capital has found its way into legitimate mining in Canada, and recently large in-

terests have been acquired by us in the Pictou coal field, to which point not a few miners from Belgium will find their way.

Your new railway lines will also place mining on a better footing and bring out new and valuable properties now unworked. As I understand it, the finding of your most valuable mineral deposits is attributable to railway construction, thus giving credit to the new lines building it is possible to anticipate newer fields and a larger output in the near future.

THE DINNER HOUR.

By John Ravenor Bullen.

We slacked her down at the dinner hour and bundled out under a tree,
Did Solomon Jopp and "Hurricane Hank," and Joe, which is the same to me.
"You can say what you mind," said Solomon Jopp, as he fanned his face with his hat,
"This drillin' fer oil's a pretty fine game—but you never knows where you're at."
"That's right enough," said "Hurricane Hank," as he swallered a chunk of meat
And savagely spat at a yeller wasp that buzzed in the blazin' heat.
"There's ways," said he, "as I've always said, for makin' a mint of gold,
But it's always the ones as should get the luck, it's always them as gets sold."
"It's true," said Solomon Jopp, "it's true, we never have had no chance"
As the wasp stung Hank on the tip of his ear, and he danced a Salome dance.

"Now you calls to mind," said Solomon Jopp, "the man from Jingermeror,
Who comed with a million of money and meant to make a million more.
He'd twenty-six alphabets after his name and the devil knows what beside,
And a portable hencyclepedia called 'The Oil-well Driller's Guide.'
He staked out the territ'ry down to the west and hired out a triplet of rigs,
And the whole blamed country near died with delight, from Gilligan down to Giggs.
Well, he punctured the earth like a pepper-pot lid with a hundred of holes and more,
And he punctured a hole in his million of gold ere he left for Gingermeror."
"Correct," said "Hurricane Hank," "correct," as he sprawled in the shade of the tree
And chewed big chunks of tobacco down on the top of the cakes and tea.

"On the nethermost hand," said Solomon Jopp, as he blinked a dusty eye,
"There was Jonathan Blob, the laziest squab, which none will ever deny.
He drilled one well in Tillarmeroo and now he's a big-money shark,
And he's counting his dollars all day and all night, seven million ain't far off the mark.
He's rigged all the time in the slickest of styles, 'nough to make a blind quadriped jump,
Wears a shiny top-hat, drinks his glass of champagne—him!! the darnedest that ere wrenched a pump.
You can say what you mind," said Solomon Jopp, as he harpooned his knife through his hat,
"This drilling fer oil's a pretty fine game, but you never knows where you'e at."
Then we cussed and cussed as we always cussed when we left the shade of that tree,
But we started her up as we always did, did Solomon, Hank, and Me.

PERSONAL AND GENERAL.

Mr. Thomas Kiddie has returned to Vancouver from a visit to a deposit of magnesite and some gold properties in Atlin district, B.C.

Mr. Elias Rogers, of Toronto, president of the Crow's Nest Pass Coal Company, Limited, visited Vancouver and Victoria, B.C., during July.

Mr. Lionel E. Hill has been appointed assistant to Mr. Ernest Levy, of Rossland, B.C., manager for the Le Roi No. 2, Limited, and the Van Roi Mining Company, Limited.

Mr. O. B. Smith, superintendent of the Granby Company's mines at Phoenix, B.C., lately visited the Hidden Creek Copper Company's property at Goose Bay, Observatory Inlet, B.C.

Mr. Andrew Bryden, formerly manager of the Dunsmuir colliery at Extension, Vancouver Island, B.C., is to superintend the work of opening new coal mines in the Nicola district for the Coal Hill Syndicate.

Mr. E. Hodgson, of Victoria, B.C., well known in connection with coal mining on Vancouver Island, recently spent a short time in the Lethbridge district, Alberta, on business connected with coal and oil prospecting.

Mr. Frederick H. Morley, M.E., of Denver, Colorado, U.S.A., has been commissioned to obtain information relative to mining properties in Portland Canal district, British Columbia, whence he went about the middle of July.

Mr. J. L. Howard, of San Francisco, California, president of the Western Fuel Company, lately paid one of his periodical visits to his company's collieries near Nanaimo, Vancouver Island, B.C. Only recently he returned from a trip to England.

Mr. C. H. Dickie, of Duncans, B.C., managing director of the Portland Canal Mining Company, has gone to Portland Canal to witness the commencement of ore concentration operations in the mill the company expects to have running in August.

Mr. Wm. Fleet Robertson, Provincial Mineralogist, left Victoria on July 11 for the Chilcotin country, in the southern portion of Cariboo district. He will make an exploratory examination of parts of Clinton and Bella Coola mining divisions, which lie between Fraser River and the Coast, about parallel 52 to 53.

The Jeffrey Manufacturing Company, main office and works, Columbus, Ohio, are changing the location of their Denver office from No. 1711 Tremont Place, and after August 1st will occupy a commodious suite of rooms in the First National Bank Building. This company besides maintaining a large selling force in over a dozen of the leading cities of this country, also maintain a corps of engineers at their branch offices situated in the following cities: Chicago, St. Louis, Denver, Montreal, Pittsburg, Charleston, W. Virginia, Boston, New York, and Birmingham. There are also nearly 100 Jeffrey agencies in additional cities in this country and abroad.

ON THE DISTRIBUTION OF ASBESTOS DEPOSITS IN THE EASTERN TOWNSHIPS OF QUEBEC.

By John A. Dresser, Ottawa, Ont.

(Published by permission of the Director of the Geological Survey of Canada. Annual Meeting, Toronto, 1910)

Introduction.

At the last meeting of this Institute a short paper was presented by the writer on the mode of occurrence of asbestos and chomite in the Eastern Townships of Quebec.*

In the interval further work has been done in the area, under the auspices of the Geological Survey, and certain relations have been ascertained between the productive and the unproductive parts of the serpentine belt in which these minerals occur. It is the purpose of this paper to show some of the geological relations of the serpentine belt and how they determine the distribution of the mineral deposits, and to apply the conclusions as an aid to prospecting for and estimating the value of further discoveries. For these purposes a brief review of the district is necessary.

Review of the District.

The part of the province of Quebec which lies south of the River St. Lawrence consists of a portion of the wide flat valley, or a plain bordering the St. Lawrence, and a hilly region, extending from the plain to the boundary line between the Province of Quebec and the United States. The northeastern part of the hilly region in the Gaspe Peninsula forms the Shickshock Mountains; the southern part is generally known as the Eastern Townships. It is to the latter part of the region, and especially the portion between the St. Francis and Chaudiere Rivers, that this paper relates. These rivers are about 100 miles apart, and from the area between them all the asbestos and chromite hitherto mined in Quebec has been obtained.

Series of parallel ridges running northeast and southwest are the principal features in the relief of the district. These are grouped into three principal ranges which are about twenty-five miles apart. One of these extends along the international boundary line near Lake Megantic, a second forms the hills of Capelton, Stoke and Weedon, passing near the city of Sherbrooke, and the third forms the hills of Broughton, Leeds and Ham, and farther to the southward rises into Sutton Mountain.

Sutton Mountain, the highest point in the district, has an altitude of nearly 3,100 feet. Several other hills rise 2,500 feet or higher, and there are considerable areas which are between 1,500 feet and 2,000 feet above sea level. The St. Lawrence plain varies in elevation from 100 to 400 feet.

The district is drained by the Chaudiere, Becancour, Nicolet, St. Francis and other rivers which cross the ranges of hills in a northwesterly direction and empty into the St. Lawrence. The tributaries of these rivers occupy the structural valleys between the ridges, and generally run either in a northeasterly or southwesterly direction. They frequently empty into the larger rivers by falls or rapids and so furnish some of the principal water powers of the district, such as the falls of the Magog at Sherbrooke, or the Wattopekah at Windsor Mills.

The Quebec Central and the Grand Trunk Railways give easy access to the greater part of the mining district. The principal mines are near the stations of Thetford Mines ,Black Lake and East Broughton on the former, and Danville, on the latter line of railway.

Mineral Production.

Asbestos (chrysotile) is the most important mineral now mined in the Province of Quebec. It comprises in value about half the total mineral production of the province and in 1907, the latest date for which full returns are available, this district furnished 84 per cent. of the world's supply.

The mineral was discovered in Canada in the early days of the Geological Survey, about 1847, and thirty years, later, 1877, it began to be commercially developed. Since that time there has been a constantly-increasing production, as may be seen by reviewing the production* of one year in each decade since the industry was begun:

Year 1878 production	50 tons	value....	$.....
Year 1888 production	4,404 tons	value....	255,007
Year 1898 production	16,124 tons	value....	471,131
Year 1908 production	66,548 tons	value....	2 555,361

The increase in production during the last decade has also been accompanied by a marked increase in price. To quote from the returns of production by Mr. McLeish, cited above, "The statistics indicate that during the past six years there has been only a slight increase in the quantity shipped as crude, although the average price has nearly doubled; while, on the other hand, the shipments of mill stock have increased over 125 per cent., with an increase of over 50 per cent. in the average price per ton obtained."

To state this in concrete form, the average prices of crude asbestos and mill stock in 1903 were $115.46 and $19.79 respectively; in 1908, $200.04 and $29.84.

In consequence of the successful development of the industry in recent years, prospecting is active and the search for new productive areas is being vigorously prosecuted.

Geology of the District.

General.—The central parts of the main ranges of hills are composed of igneous and sedimentary rocks of early age, in part at least Pre-Cambrian. Flanking these are sediments of later Cambrian and Ordovician age, within which are isolated intrusions of granite which are believed to have been injected in Devonian time. On the southeast side of the Sutton and Leeds range of hills there is a series of basic intrusive rocks generally known as the Serpentine belt. It is in this that the asbestos and chromite deposits of the Eastern Townships are found.

Local.—The sedimentary rocks of the district are schists, slates, sandstones and quartzites of Cambrian and Ordovician age. They are highly altered rocks and much distributed in position by folding and faulting. They have a general northeasterly strike and dips at high angles.

* "Mineral Deposits of the Serpentine Belt of Southern Quebec." Journal of the Canadian Mining Institute, Montreal, 1909.

* "The Production of Asbestos in Canada," 1907-8." By John McLeish, Chief of Division of Mineral Statistics, Department of Mines of Canada.

The igneous rocks in which the mineral deposits occur are all intrusive in the sediments. They have been injected at different times, although many of the different varieties of rock have been formed by differentiation from a single intrusion. At the contact of the intrusives with the sedimentary rocks large amounts of breccia have been formed, the sediments are baked and hardened, yet dykes are rare and there has not been any notable fracturing of the sediments. The intrusions have been gradual in their action.

The area occupied by igneous rocks is often and conveniently called the "serpentine belt," since serpentine is the rock which contains the principal mineral deposits. Thetford, through the Townships of Thetford, Coleraine, Wolfertown, Garthby, South Ham, Wotton, Tingwick, Shipton and Cleveland. It probably also forms a large part of the serpentine belt further to the southwestward in the counties of Sherbrooke and Brome; but this area has not yet been studied in detail. The country rock of the mines at Thetford, Black Lake and Danville belongs to this series.

The rocks of this phase are believed to have been formed by differentiation from a single magma. Serpentine is metamorphic rock that has been derived by alteration from peridotite and in the hand specimen it is not easy to distinguish one from the other. They are both com-

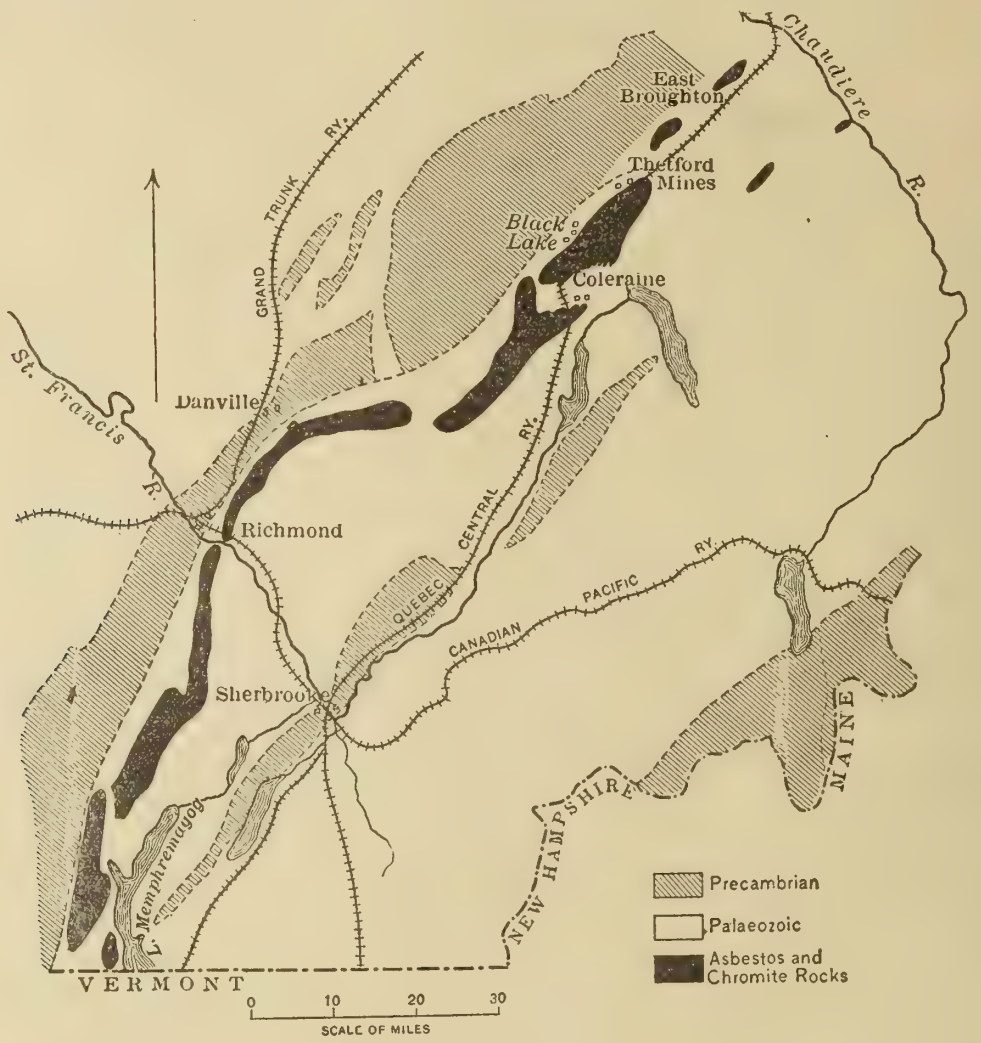

Fig. I.

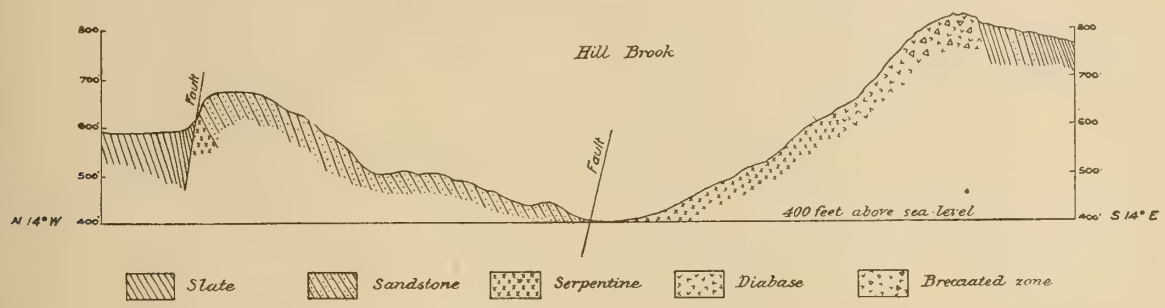
In the serpentine belt two phases of igneous rocks may be distinguished which differ in the values they contain, in the state of preservation, and perhaps also in age. They will be referred to as the Thetford phase and the Broughton phase from townships in which they are well developed. Their general characters are shown by a comparative view of the rocks which compose them.

Thetford Phase:—Serpentine, Peridotite, Pyroxenite, Gabbro, Diabase, Porphyrite, Granite, Aplite.

Broughton Phase:—Serpentine, Soapstone, Greenstone schists.

Thetford Phase:—The Thetford series makes up the principal part of the serpentine belt. It includes the band of igneous rocks that extends southwesterly from Broughton Mountain near the northeastern boundary of monly called serpentine. Pyroxenite is a fairly distinct rock, being often coarse grained. Gabbro, diabase and porphyrite are conveniently grouped under the name of diabase in the field, since they pass into one another by gradual transition and are not easily distinguished. Granite—in its fine grained acid phases aplite—is sometimes differentiated *in situ* from the other rocks, in others it has been intruded a little later showing the differentiation to have taken place previous to intrusion.

Broughton Phase.—The rocks of the Broughton phase form a narrow band that extends from range III of the Township of Broughton southwesterly as far as the Robertson mine in Thetford. Through several ranges in Broughton it is confined to lot 13, but crosses the township towards the northwest as far as lot 2 in range XI.



In Thetford it occurs principally in range V. Similar rocks also appear in ranges I, II and III of Tring, in or near lot 24, at the D'Israeli Asbestos Mine in Garthby range III, lot 16, and in other isolated areas in Leeds and Ham.

This phase contains the mines and prospects of East Broughton and those in the vicinity of Robertson.

The rocks have not yet been examined in detail, but they resemble the rocks of the Thetford phase in essential respects. The chief difference is in the state of preservation of the rocks, although there may have been also difference in their original composition. Probably they originally contained more pyroxenite. In the Broughton phase there is little, if any, peridotite accompanying the serpentine, which indicates that the alteration to serpentine is nearly complete.

sometimes extends to the top or outer edge of an intrusion, but the acid rocks whenever present are nearest the tops of sheets or the margins of other intrusions. Thus between the Danville Pinnacle and the St. Francis River, a distance of eight miles, the serpentine belt is in the form of a thick sheet dipping to the southeast at a high angle. Serpentine occurs along the northwest or footwall side, and diabase wherever present is on the southeast or upper side. The mines at Asbestos are in similar position with regard to the pyroxenite and diabase hills on the southeast and may be on the northeasterly extension of the sheet referred to above.

At the Robertson mine in the 16th lot of the range of Thetford, serpentine forms the lower or northwestern half of a sheet dipping southeast at an angle of 50 degrees, and schistose diabase the upper or southeastern portion.

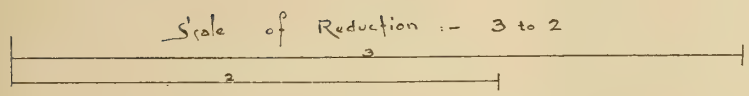

Fig. II

In the place of pyroxenite, which appears in the Thetford phase, there is its alteration product, soapstone, in the Broughton phase. The greenstone schists of Broughton probably had originally a composition similar to the diabase, or some closely related rock, in Thetford. Like the Thetford phase, they are doubtless differentiated from a single magma.

Granite has not been found in the Broughton phase, except in an isolated occurrence in range I, lot 24 of Tring, nor are any important bodies of chromite known in these rocks. These are the principal indications of different original composition in the two phases.

Structure of the Igneous Bodies.

The rocks of the Broughton phase and portions of the Thetford phase occur in bands, which follow the dip and strike of the enclosing sediments, and thus form sills or intrusive sheets. Other portions of the Thetford phase occupy elliptical areas sometimes narrowly connected with one another which are uncovered portions of a batholith or thick laccolith. The rocks are arranged in the following order: 1st, serpentine; 2nd, pyroxenite; 3rd, diabase,—in sheets, from the base upwards; in batholithic masses, from the centre outwards.

Where serpentine is in excess of the other rocks it Several exposures in Broughton show soapstone in the upper, and serpentine in the lower parts of a sheet.

This arrangement of the rocks agrees with the relative basicity, and density of the principal minerals, and with the order in which they generally crystallize.

Order of Crystallization.		Specific Gravity.	Rocks Formed
1.	Olivine	3.32	Peridotite (Serpentine)
2.	Pyroxene	3.20	Pyroxenite (Soapstone)
3.	Feldspar	2.70	With pyroxene forms, diabase, etc.

Olivine crystallizing first would, in the lighter portion of the magma remaining fluid, settle towards the bottom of the sheet, even if at a high dip, and form peridotite, which later has been altered to serpentine. Closely following olivine, pyroxene crystallized and likewise settled, forming pyroxenite. By later alteration this has become soapstone.

Where pyroxene and olivine became mixed together, probably through crystallizing simultaneously, they formed by alteration the harder variety of serpentine in the Thetford phase, or the talcose serpentine of the Broughton phase.

Where pyroxene was mixed with feldspar, which crystallized next in general order, diabase and the related rocks were formed. This separation would be more nearly complete, the more slowly the cooling took place.

Granite has been formed in sheets in only two cases as far as known. On lot 24, range I of Tring, it occurs as a differentiate at the top of the sheet. In the other instance, in the Townships of Cleveland and Danville, it appears to have been injected later than the serpentine in which it occurs principally as dykes.

In the areas that are regarded as uncovered portions of a batholith, such as the hill between Thetford Mines and Black Lake, or between the west side of Black Lake and the Wolfestown road, the Belmina road, or the area about Little Lake St. Francis, serpentine occurs in the central part and is partially, or wholly, enclosed by pyroxenite, which in turn is generally bordered by a rim of diabase. The outer edge of the diabase usually contains fragments of the adjacent sediments and so passes into breccia. The accompanying cut (Fig. 3) shows the arrangement of the rocks as seen along a section from the Thetford River to Bisby Creek. The section follows the power line of the St. Francis Hydraulic Company from the property of the Dominion Asbestos Company southward.

A mile northwest of the northern end of this section the sediments dip towards the southeast at an angle of 70 degrees, and within a few yards of the contact, four miles northwest of the section, the dip is 75 degrees in the same direction.

The first igneous rock is diabase which in the outer portion sometimes contains fragments of sediment forming a breccia. The diabase may be seen near the Roman Catholic church in Black Lake. The section is then drift covered until the serpentine is reached near the lake road. Following the line of section, the serpentine continues across the hill above the Standard and Dominion mines, though with a considerable amount of pyroxene in the higher and southern part of the hill, and passes beneath a heavy covering of drift. Near the Quebec Central Railway, 560 yards north of Chrome siding, there is an exposure of pyroxenite and diabase at the south side of this serpentine area.

The drift covered area extends for two miles along the line of section until the second area of igneous rocks is met. This consists of breccia, diabase, pyroxenite, serpentine, pyroxenite, diabase and breccia in succession. The succeeding sediments stand vertically for half a mile south of the contact and at a distance of two miles dip towards the southeast at an angle of 75 degrees.

It will be noted that Thetford River and Bisby Creek occupy similar positions in erosion valleys, cut in the transition rock between the diabase and serpentine; that the general dip of the sediments on either side of the belt is southeasterly and that the dip, which is practically vertical near the contact on either side, is generally higher on the southeast than on the northwest.

No sediments have been found in the drift covered part of the section, but three miles west of the section, sedimentary slates strike towards this area nearly at right angles to the line of section. They dip away from each of the igneous ridges thus indicating a synclinal trough between them, which has been deeply filled with drift.

The structure of the serpentine belt as shown in this section, suggests a thick laccolith similar to that which contains the nickel deposits at Sudbury, but further investigation does not support the comparison very well. Parallel ridges such as occur here are not common, being found in only a few instances in the distance of nearly 100 miles thus far examined. Such cases seem to represent the dying out of one intrusive ridge and the beginning of another near and parallel to it.

The dip of the sedimentary rocks is in the same direction on either side of the belt and at high angles. The arrangement of the rocks in the two ridges is the same, while if they were parts of a laccolithic sheet they should appear in reversed order on the two ridges. It, therefore, seems probable that the igneous ridges are formed along two lines, perhaps minor anticlines, which have

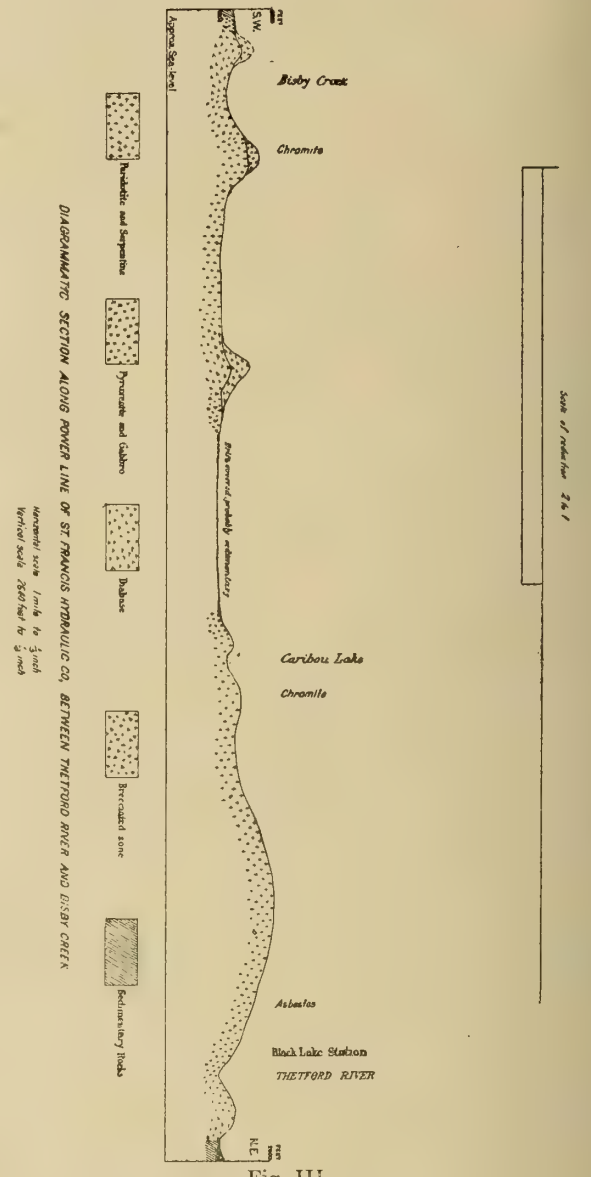

Fig III

afforded an easier ascent for the magma. They may be connected at no great depth beneath the sediments, yet they diverge sufficiently to permit of similar effects from differentiation taking place in each.

The arrangement of rocks by which the most basic rock is at the centre and the mass becomes more acid towards the outer edge is a common one in igneous intrusions of this class. It is theoretically accounted for by differentiation according to gravity taking place in a slowly-rising magma, thus bringing the more acid material, which formed the diabase and related rocks everywhere, in contact with the sediments. As the intrusion gradually rises, the acid margin is carried upward, forming an envelope over the advancing batholith. This is

seen in this district in such hills as Broughton, Adstock, and Big Ham Mountains which rise in cone, or saddle shapes, and are encased in diabase in the upper portions. Near the bases of these hills the diabase passes into gabbro, and where erosion has been especially heavy, pyroxenite and in places serpentine are exposed.

Location of Deposits.

Thetford Phase.

Character of the Rock.—The asbestos deposits of the Thetford phase of rocks are found only in the purest serpentine. This in a general way is indicated by softness of the rock, but serpentine impure from the presence of soapstone is also soft, but is not as valuable for asbestos. Therefore soft serpentine is favourable for asbestos only when there is no soapstone present.

As shown in the arrangement of the rocks above, the purest serpentine occurs in the lower parts of sheets and in the central portions of batholithic masses. As the trend of the serpentine belt is northeasterly, sheets in this district must dip either to the southeast or northwest. Where sheets dip to the southeast, as between Danville and Richmond, the best rock is found along the northwest side of the serpentine belt. In Garthby range II, where the dip is to the northwest, the best rock is near the southeast side of the intrusion.

In batholithic masses the purest serpentine, which would be found at the centre were the mass reduced to a horizontal plane surface, is best exposed around bases of the peridotite-serpentine hills, but especially near the north side. Thus the mines of Thetford are at the extreme northern edge of the serpentine hill which extends southwards to Caribou Lake, and the mines of Black Lake are situated along the northwest side of the same hill. The King mine in Ireland is on the northern edge of the hill of serpentine and peridotite which extends southward to the Lambly mine in Coleraine, while the Belmina and Chrysotile mines are on the northern and southern borders respectively of the hill which separates them.

Effects of Erosion.—The better exposure of asbestos-bearing serpentine on the north side is due apparently to glaciation, the ice having eroded the hills on the north side, against which the glacier moved, more deeply than on the south, or lee side. While equally good serpentine may, and probably does, extend around and through these central hills it is generally covered by harder and less productive rock except where erosion has been especially heavy.

Asbestos has been found on the south side of two of the larger hills, at Chrysotile, and at the old Lambey mine near Coleraine, but the northern side has thus far proven more productive.

Serpentinization.—Besides the purity of the original peridotite, and its exposure by erosion, alteration to serpentine is a necessary condition for the formation of asbestos. The precise nature and cause of this change, from peridotite to serpentine and, consequently, the parts of the rock mass in which it is most likely to take place, are as yet imperfectly known.

Peridotite is a rock consisting principally of the mineral olivine, which is composed of silica, magnesia and iron. In the change to serpentine, water is taken in to the amount of about 12 per cent., while iron and silica are probably in part removed. The serpentine thus produced is a softer rock than the original peridotite and shows few grains or crystal faces. Pure serpentine can thus be easily distinguished from fresh peridotite. But the greater part of the rock in the district is only partially altered to serpentine. Other conditions being equal, it appears to be more productive the farther the alteration has gone. Consequently the degree of alteration must be taken into account, and this is a somewhat difficult feature to determine. Hardness is in part a guide, but examination by means of the microscope is often necessary to certainly determine the degree of alterations of the rock.

An important part, at least, of the change from peridotite to serpentine is due to the action of water. Whether this is due to meteoric waters such as now circulate through the rocks, or to magmatic waters which came in with intrusions of igneous rocks is a question for further investigation, as it bears on the importance of the granites as an indication of asbestos. But in any case the water reached the rocks, which it has altered, by means of fissures and fractures which are, consequently, an important indication of the part of the rock mass that is likely to be best serpentinized and to contain asbestos.

Fractures.—The parts of the rock mass which are altered to serpentine appear to depend in a considerable measure at least on the amount of fracturing of the rock, which is also a necessary condition for the forming of asbestos veins.

Where there has been much fracturing the rock is largely or wholly serpentine. Where other openings are not found the peridotite is commonly serpentinized along joint planes. In such cases veins of asbestos sometimes occur in a rock which, on the whole, is still a comparatively little altered peridotite. The hills on the south and west sides of Black Lake furnish a good example.

Serpentinization seems to proceed from any crevice into the wall rock on either side, and is generally followed by the formation of asbestos veins proportional in width to the band of serpentine. The asbestos veins in such cases are about one-third of the width of the serpentine band on either side of them.

The degree of serpentinization of the rock as a whole, and the amount of asbestos thus depends in a measure on the amount of fracturing. The fractures may be joints, or cleavage planes due to regional foliations, or the casting off of concentric shells from rectangular joint blocks probably induced by increase of bulk due to hydration.

Fracturing is thus both a cause and an effect of serpentinization. But in either case it is an indication of well serpentinized rock, provided the peridotite were originally pure.

Where the rock is too greatly fractured the veins of asbestos become so short as to be of little or no value. Thus when serpentine is in contact with sediments it is usually finely shattered and the asbestos, if any, is too short to be useful and occurs as slip fibre. The shattering of serpentine near the contact also suggests a primary gneissic structure, but a determination of the full cause of it requires further study.

Influence of Granite.—As a result of experience the presence of granite in an area of serpentine is generally regarded as a favourable indication of the occurrence of asbestos but the casual connection, if any, is not easily apparent. Granite is often contemporaneous with the diabase and in some cases also with serpentine. In such cases the granite is in irregular masses, and it is difficult to see what connection they could have on the occurrence of asbestos beyond indicating a very complete differentiation of the rock.

In other cases the granite has been intruded a little later than the other rocks and forms dykes and sills. The fracturing which was accompanied by the injection of these dykes would favour the development of

asbestos veins. Hence it is possible that they may be effects of the same cause, rather than that granite is any part of the cause of the occurrence as asbestos veins. It is possible and perhaps probable, as has been suggested by Dr. A. P. Low,* that the action of heated waters accompanying the injection of the granite dykes has aided in the serpentinization of the peridotite.

Broughton Phase.

The serpentine of the Broughton phase differs from that of the Thetford phase in being finely shattered and in containing asbestos principally in the form of "slip" or parallel fibre. It is also softer than the rock at Thetford and often has a talcose feel. Deposits of soapstone and sometimes of talc are found associated with it. It carries very little chromite even in disseminated grains and no deposits of important size. There is also no granite in the Broughton and related rocks, except in an isolated occurrence in the Township of Tring, which probably belongs to this series.

The whole series occurs in intrusive sheets with the serpentine at the base, soapstone and greenstone schist, when present, in ascending order to the top of the sheet. In some cases, however, serpentine makes up the whole or greater part of the sheet and so extends to both walls.

In the serpentine there are blocks and masses of a harder rock which have not yet been examined microscopically and which contain no asbestos. These occur more plentifully towards the base of the serpentine and often make up the greater part of the rock near the lower edge of the sheet. Accordingly the pits are usually situated a little above the extreme base of a sheet.

Summary.

The results of this investigation which seem to have a practical bearing on the location and estimation of asbestos, may be briefly summarized. Aside from the evidence of asbestos actually seen, the conditions which it is important to observe as far as known are:

1. Purity of the serpentine.
2. Fracturing.
3. Presence of granite.

1. The purity of the serpentine is the most important feature. It depends on (a) the purity of the peridotite, or original rock. (b) Its degree of serpentinization.

(a) The purity of the original rock depends on the composition of the magma and its differentiation in cooling, the latter factor being largely influenced by gravity. The purest serpentine is accordingly found at the base of sills, or intrusive sheets, and in the central portions of batholithic masses.

The exposure of the central parts of batholithic masses in this district depends in a large measure on glacial erosion, which, in this district, has uncovered the most productive rock on the north side of the larger hills.

(b) The fractures are due to jointing, and regional compression; also probably to the increase of volume accompanying serpentinization and possibly to original flow structure around the margin of batholithic intrusions. Hence they are likely to be more abundant around the edges of serpentine and in zones of special regional foliation.

3. The granite, where intrusive, has accompanied a fracturing of the peridotite, a condition which is favourable to the formation of serpentine and asbestos. Magmatic waters accompanying the intrusions may also have aided in serpentinization. Granite dykes are, therefore, thought to be a favourable indication of the presence of asbestos veins.

*Report on the Chibougamau Mining Region, Geological Survey of Canada, 1906.

THE CLAY AND SHALE DEPOSITS OF NOVA SCOTIA AND PORTIONS OF NEW BRUNSWICK AND PRINCE EDWARD ISLAND.

By Heinrich Ries.

(From Summary Report of Geological Survey.)

The investigation of the shale and clay deposits in the above-named region occupied the summer of 1909. The writer was assisted in the work by Mr. Joseph Keele. The object of the study was to ascertain as far as possible what geological formations were clay and shale-bearing, and which of these deposits were adapted to the manufacture of clay products.

With this end in view, the clay and shale deposits were examined as thoroughly as was possible in the time at our disposal; and samples were collected for testing in the laboratory. The last was an important part of the work; since one can tell but little from the appearance of the material in the field.

The different brick plants in operation were also visited, and samples of their products taken for crushing, transverse, absorption, and freezing tests.

Nova Scotia.

The geological formations of Nova Scotia range from the Pre-Cambrian to the Triassic, and they are overlain nearly everywhere by a mantle of pleistocene material of variable thickness.

In certain formations the character of the material is such that there is little probability of its being of any value to the clay-working industry, and these are considered first.

Formations of No Probable Value to the Clay-worker.

Pre-Cambrian.—This consists of crystalline rocks of either igneous or metamorphic character, which underlie a large portion of southwestern and southern Nova Scotia proper, and a large part of northern Cape Breton, as well as scattered areas in southeastern Cape Breton. None of the Pre-Cambrian rocks are of plastic character, nor do they become plastic when finely ground. They have no doubt been weathered to residual clays in the past; but these have probably been removed by glacial action. Only one deposit of residual material came to our attention, and this was a pocket on Coxheath Mountain, near Sydney, the clay there having evidently been formed by the decomposition of a light-coloured felsite, which occurs in some abundance in that region. The clay deposit is too small to be of any economic value. In recent years several attempts have been made to utilize this rock in the manufacture of firebrick, but up to the present time they have not been successful. Unfortunately some

persons have promulgated the idea that the felsite could be used by itself for brick manufacture; but this is impossible, since the material is lacking in plasticity, and could not be utilized unless some bonding material was mixed with it. If a good fireclay could be found in the neighbouring Sydney coal field, it might serve as a binder for the felsite.

It is possible that veins of feldspar or quartz of sufficient purity and thickness to be workable, might be found in the Pre-Cambrian area, but diligent inquiry failed to discover any.

Silurian.—The rocks of this system underlie a narrow area on the south side of the Annapolis Valley, and irregular areas in the eastern half of Pictou and northern half of Antigonish Counties. They are economically important because of the deposits of iron ore which they contain. Associated with these are somewhat extensive beds of shale, but most of them are rather slaty in their character, and of exceedingly doubtful value for the manufacture of clay products. On weathering they might produce plastic clays, but even so, the majority of them would be rather ferruginous. A few samples were collected for testing, in order to definitely determine their value.

Devonian.—The Devonian rocks underlie a narrow bel tof irregular width extending through the central part of the province, and underlying some small areas in southwestern Cape Breton, to the northeast and southwest of St. Peter Bay, as well as on the northeastern side of the Straits of Canso, near Hastings.

These rocks were examined at a number of localities, and were found to be either too schistose in their character, or where of argillaceous nature contained too much silica, present either as disseminated sand in the shale, or interbedded sandstone layers. Were it not for the sandstone layers, the material, though siliceous, could no doubt in some cases be used for brick manufacture.

Permian.—This underlies a discontinuous area extending from Chignecto Bay eastward along the north shore to a little beyond Merigomish harbour. No shales of any value were found in it.

Triassic.—The Triassic rocks form one belt following the Annapolis Valley, and another one along the north shore of Cobequid Bay, tapering out east of Truro. They are usually sandy in their character, and not to be looked upon as a source of either clay or shale.

Important Clay-bearing Formations.

From what has been said above, it will be seen that the formations likely to yield clay or shale deposits of value muts be the lower Carboniferous, Millstone Grit, Coal Measures, and Pleistocene. These are few in number, but nevertheless they underlie areas of considerable size.

Lower Carboniferous.—Underlying, as they do, a rather extensive area in central Nova Scotia, and another in Cape Breton, it is to be regretted that the lower Carboniferous rocks, it is to be regretted that the lowed into by clay-product manufacturers. The formation is, however, somewhat variable in its character, carrying, as it does, beds of shale, conglomerate, gypsum and limestone. Those shales closely associated with the gypsum beds may be of value for common brick manufacture, although they frequently contain considerable quantities of impurities, such as gypsum nodules, concretions of iron carbonate, or sandy streaks. At some points though, as near Pugwash, the shale occurs in large beds, and works up well to a plastic mass: the more so as it is slightly weathered. At that locality it supports one of the most active and best equipped brick plants in the province.

Northeast of Shubenacadie, also, promising shales were found in the lower Carboniferous, while in the so-called limestone series around Sydney there were found a number of beds which appear promising for brick manufacture, provided the sandstone layers do not occur too thickly.

Millstone Grit.—This is well exposed in the area north of the Pictou Coal Measures; south and southeast north of the Pictou Coal eMasures; south and southeast of Hawkesbury; and west and southwest of the Sydney coal field.

One cannot predict the universal distribution of promising clay or shale beds in the Millstone Grit, but small beds are not uncommon. Unfortunately, outcrops are scarce in many of the areas underlain by the rocks of this age, which increased the difficulty of finding clays or shales in it. Several deposits of fair importance were seen, and may be referred to in passing. In the Sydney region, a pit has been opened near the Steel works, exposing a bed of soft bluish shale, not less than 5 feet in thickness. A second deposit occurs near the coke oven plant of the Dominion Iron & Steel Company, and a third one outcrops along the east shore of Sydney harbour, near Victoria Mines post-office. Although the tests of these have not yet been completed, it is highly probable that they represent a grade of material considerably higher than brick clay.

In the Pictou coal region, a rather heavy bed of mottled, shaly clay has been found northeast of Woodburne station, on the Intercolonial Railway. Preliminary tests have shown its adaptibility to the manufacture of pressed brick. It may be said here, that there is some doubt as to whether this bed lies in the Millstone Grit or Permian conglomerate, but the former view seems the more reasonable .

The Millstone Grit contains at least one shale bed of some thickness in the Joggins area; but it is probably of red burning character.

(To be Continued.)

CORRESPONDENCE.

Editor Canadian Mining Journal,
Toronto, Ont.

Sir:

Noting the suggestion in your Rossland correspondence in issue of May 1st that the new Canadian dollar be made of some more valuable metal than silver, I would suggest—though very likely this has occurred to others before me—that the Canadian dollar be composed of an alloy of gold and silver. The silver dollar is entirely too large, especially if any attempt be made to give a dollar's worth of silver in the coin, while the gold dollar is uncomfortably small.

It might be urged against this plan that it would offer opportunities for counterfeiting, but I cannot see that the metallic composition of the coin would in any wise have any tendency to give counterfeiters a greater opportunity than they now have with ordinary gold and silver coins.

It seems to me that such a coin as suggested would be distinctive, as well as in every wise satisfactory.

Very truly,
Horace J. Stevens,
Editor the Copper Handbook,
Houghton, Mich.

Mr. C. L. Hower, late of Johnson, Pennsylvania, is supervising development work on coal properties in western Alberta for the German Development Company, of Ottawa.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

The Montreal "Witness," July 11th, had a short editorial comment on fatalities in English coal mines. The "Witness" comments on the fact that in 1908 thirteen hundred persons lost their lives in mines, and refers to a recent debate in the British House of Commons concerning the Whitehaven disaster. The "Witness" remarks that "the one cheerful feature of the debate was the information that advance in life-saving has been made, and that in fifty years the fatal accidents have been reduced from five per thousand to less than one and one-half per thousand of the men employed. But the figures for 1908, as one member remarked, are still an indictment of the management of the pits." It should be remembered in considering these figures that in the fifty years referred to by the "Witness" the decrease in loss of life in coal mines has been accompanied by an increase in the tonnage of coal produced, which, for so small a country as Great Britain, is nothing less than remarkable. Reflections on the management of British coal mines will come more gracefully from Canadian newspapers when the accident rate in Canadian coal mines compares more favourably with the British fatality rate than is the case to-day. Although when the rate of mine fatalities in Canada is compared with that of the United States we have cause for congratulation, yet, unfortunately, we have fully as much cause for reflection when our figures are compared with those of Great Britain, France and Belgium.

The "Witness" refers to the Home Secretary's action in introducing a bill to the British Parliament for the organization and training of rescue corps. While we have no wish to depreciate the value of these appliances and the necessity for their adequate provision and the training of men in their use, yet it must be remembered that the proper way to reduce accidents is by preventing as much as possible the causes from which they arise. Your correspondent has on several previous occasions pointed out that the term "rescue apparatus" is a misnomer. The probabilities of being able to rescue any large number of men at coal mine explosions is always open to grave doubt. Up to the present time, and, we think, in the future, the proper use of breathing apparatus will be in checking the growth of incipient fires by enabling the underground fire brigade to approach within effective range of the fire, and in preventing such a fire from developing into a disastrous conflagration with dire results to both life and property. We have always argued that the provision of breathing apparatus, accompanied by the proper training of men in their use, is needful and should commend itself to every mine owner who has any regard for life or property; but their general use is not likely to be followed by any marked decrease in the fatalities incident to coal mining. The great majority of coal mine fatalities arise from falls of roof and side and from accidents connected with the mining machinery. On this source of fatalities the provision of breathing apparatus and the erection of rescue stations can, of course, have no effect whatever. If the Montreal "Witness" will compare the Canadian coal production of 10,500,000 tons per annum with the British coal production of 270,000,000 tons and put side by side with these figures the number of lives lost in the coal mines in each case, they will realize that if the British figures are to be considered as an indictment of the management of the pits a good deal could be said about the matter on this side of the water.

The Technical Education Commission.

The Federal Commission on Technical Education is expected to sit at Glace Bay about the beginning of August. From the remarks of the Chairman of the Commission at the opening sessions in Halifax the scope of this Commission's enquiry seems to be much wider than would be expected from the name that has been given to it. All matters affecting the general environment of industrial workers will apparently be taken under review. Preparations are being made to have representative officials and workmen of the collieries give evidence before the Commission, and it is expected that the members of the Commission will visit the coal mines themselves and thus gather their information at first hand.

The Colliery Relief Societies.

The new scale of contributions and relief which resulted from the consolidation of the Colliery Relief Societies of the Dominion Coal Company, came into effect on the 1st of July, and deductions are now being made on the new basis. The relief payable to members is exceedingly liberal and should prove adequate to take care of all ordinary cases of sickness and accident. The members' monthly contribution is fifty cents, and the Coal Company will contribute equally with its employees. The weekly benefit for disability caused by sickness or accident is six dollars. In the case of death an immediate benefit of one hundred dollars is payable, and the widow will receive eight dollars per month for five years, with three dollars per month for each child until the age of fourteen years. Thus the widow of a member having four children would receive an income of twenty dollars per month for at least five years, in addition to the death claim of one hundred dollars. Provision is made for special grants to members suffering the loss of eyes or limbs. Each local branch will manage its own affairs, but all funds will be deposited in a central treasury. The general affairs of the Society will be administered by a Board of Directors on which the company and its employees will have equal representation. The assets and liabilities of the old societies have been taken over by a new society, and the Coal Company has deposited a sum equal to the accumulated surpluses of the former branches to the credit of the new society. It is expected that every employee of the company will eventually become a member of the Benefit Society, for which may safely be prophesied a long and useful life. In opening the proceedings of the first meeting of the general board of directors of the new society, Mr. Butler, the general manager of the Coal and Steel Companies, said that apparently the relations between the employees of the Coal Company and the management were entering upon a new and better era, and he forecasted for the new society that it would prove a strong factor in promoting harmonious relations between the management and their employees.

ONTARIO.

Cobalt.—A regular storm of protest is coming in from Gowganda and Porcupine, where the Government roads are being built, with the aid of prison labour. The labour unions have taken the matter up, and have petitioned the authorities to stop the practice. One of their strongest claims is that there are a great number of men in the district who are unable to obtain employment and that the action of the Government in using prisoners on the roads is taking away from these men the opportunity to make a living. The labour situation in the mining camps is quite satisfactory, although there is a considerable surplus of unemployed. During the past winter the possibilities of a strike for this summer were hinted at, but there has been no sign of it. The large element of foreign labour in the camp practically precludes a successful strike being made, and aside from that wages are so good, as a general thing, that there is very little cause for complaint.

The shipments from Cobalt for the first six months of 1910 show an increase of only two tons over the production for the corresponding period of last year. It is expected, however, that silver will show an increase of approximately two million ounces. This is due to the increased quantity of concentrates being

shipped, and the consequent falling off in the shipments of low grade ore. The Cobalt ore shipments for the six months totalled 14,915 tons, while the Gowganda output was 372 tons. The production of bullion in Cobalt for the same period amounted to 187,597 ounces.

Another new surface vein showing very high values in silver has been uncovered on the Lawson property. It was found near the Foster line and has already been traced for about 200 feet. It is irregular as to width, but where the stringers come together it shows up to twelve inches of rich ore.

The statement of the Crown Reserve for the first six months of the present year shows a profit of $536,064. The returns from ore shipments amounted to $709,569, while operating expenses and royalty charges totalled $173,505. Dividends to the amount of $530,644 were disbursed, leaving a balance of $5,420. The value of the ore on hand is estimated at $30,000.

Work has been started on the new concentrator for the Hudson Bay mine. It will have twenty stamps with an estimated capacity of sixty tons a day. An important concession has been made by the Government, by which the mining company is allowed a reduction of the royalty in the shape of a rebate for every ton of ore milled. The mine has formerly been paying a royalty of fifteen per cent. on the gross value of the output.

At the annual meeting of the Lang Caswell Company it was decided to end the pool and issue certificates to the shareholders. It was announced that a new vein four to six inches wide, and assaying about 150 ounces, had been uncovered. Only surface work is being carried on at the present time, but it is probable that underground operations will be resumed this fall. In the crosscut from the lowest level of the Little Nipissing, the No. 2 vein has been cut. The vein was wider than on the upper level and showed good values. It is probable that in the near future the winze will be sunk another seventy-five feet and a new level opened up.

Another new vein has been found on the Nipissing property near Peterson Lake. It is of good width and shows considerable silver. During the month of June this company produced 350,658 ounces of silver, valued at $185,847, and shipped silver to the value of $180,427. A new shaft has been started near the Chambers-Ferland line to develop a number of veins that have been found in that section.

The Kerr Lake has declared the regular quarterly dividend of five per cent. with a five per cent. bonus, payable Septembr 15th. When this has been paid the shareholders will have received a total of 81 per cent. on a capital of $3,000,000.

Professor Richards, of Boston, has been in camp for some time, and among other things has been paying particular attention to the different concentrators. He delivered a very interesting address before the local branch of the Canadian Mining Institute on "Recent Investigations into Ore Dressing." He stated that there was every probability of there being a fine set of mills in the near future. None of them, he believed, had gone far enough to arrive at any very definite conclusions, but they were proceeding in the right direction.

Underground work has been recommenced at the Columbus property. The company has been re-organized and is now under entirely different management.

Mr. Ludwig Rose, a representative of the German Government, has been in the district for some time past, studying different methods of mining and concentration. He is looking particularly into those properties where very high grade ore is produced.

The last few months since the introduction of power air and electricity, there has been a very considerable decrease in the gross earnings of the T. & N. O. Railway. This is largely due to the falling off in the consumption of coal, which now practically amounts to nothing. So far no figures are available relative to the saving of the new power over steam generated power. This is on account of the fact that air meters have not yet been installed, and that air is at present being sold on the basis of so much per drill per shift. That the saving is great cannot, however, be doubted. Formerly power in the camp cost on an average $150 per horse-power year. Now electric energy can be bought for $50 per horse-power year, and the air, while sold on a different basis, probably does not cost much more.

A writ of execution has been issued against the Goulds Consolidated, one of the companies leasing their ground from Peterson Lake. A part of the surface equipment has been seized.

J. S. Bradley, who has been heading the fight against the Cobalt Central management, states that he now has sufficient powers of attorney sent him by the shareholders to overthrow the present control, as represented by Thomas Nevins and his associates. He has tried to do this several times before, but up to date has not succeeded.

At a depth of twenty feet below the main level of the Waldman, to the west of the shaft, ore has again been found in the vein. On the level the values had been cut out by a fault and it was on the other side of this that the ore was picked up. In this same section of the Gillies Limit, the Wyandoh shipped its first car of ore a short time ago. Part of it was high grade and part medium.

During the first six months of 1910 the McKinley-Darragh produced almost as much silver as in the whole of the preceding year, while the Savage produced as much as in the whole of its previous history. Three veins are now being worked on this latter property, which is in splendid condition with every indication of becoming an important shipper.

The first shipment from the new mill of the Nova Scotia, consisting of twenty-six bars of silver weighing 26,700 ounces and valued at $14,685, was sent to England a few days ago. The Nova Scotia mill is a combination of pan amalgamation and cyaniding, and is a decided departure from the general run of mills in the district. The cyanide process is in use at the O'Brien, Nova Scotia and the Buffalo, the latter being the only one that has published data relative to the working costs. On this property only the slimes from the concentrating plant are treated. These averaged about 13 ounces silver and an extraction of only 66 per cent. was made. This seems very low, and it would appear that close slime concentration would work to as good advantage. Experts were called in some time ago, however, and several changes have been made in the process by which a much higher extraction is expected in the future.

A new ore shoot has been opened up on the 100 foot level of the Keeley mine in South Lorrain. Where cut the vein was about twelve inches wide of high grade ore. A big vein carrying about 200 ounces has also been found on the property of the Howard Syndicate near Ox Bow Lake.

It is stated that the Coniagas will resume its regular quarterly dividend of three per cent., which will be payable the first of August. Up to date this company has paid 29 per cent. on its capital of $4,000,000. Developments on the third level are very satisfactory, the No. 2 vein giving wider and richer ore than it did on the level above.

Porcupine.—It is stated that Mr. A. E. Wallberg, who practically controls the Mines Power, Limited, of Cobalt, has purchased a lease of a water power, on the Mattagami River, in close proximity to the Porcupine camp. It is situated in the Temagami Forest Reserve, about nine miles from the boundary of Tisdale Township, and has an estimated capacity of 6,000 horse-power under a head of 120 feet. Survey parties have been sent in to make detailed plans of the water power and to lay out roads and transmission lines. It is doubtful if work will be started before next winter, because, although the district shows every sign of becoming of great importance, development has not proceeded sufficiently to absolutely prove it. The work accomplished during the next few months, however, will go a long way toward proving up the district. The installation of a plant of this sort would prove of immense benefit to the new camp. Situated as it is at a considerable distance from the railroad, and with no immediate possibility of a branch line being built,

wood will be the only fuel available for some time to come. The immediate supply of this, however, will soon become exhausted, as very extensive developments that will require a large amount of power have been projected by some of the properties. A small stampede has lately taken place into the country around Great Pike Lake, which lies about forty miles to the southwest of Porcupine. A number of samples showing high values in free gold have lately been brought out.

Another big vein has been discovered on the Timmins property. Not enough work has been done yet to define its extent, but where opened up it shows some spectacular values in free gold. On the 100-foot level of the main shaft some of the richest ore yet discovered on the property is being found. The vein is ten feet wide and values will run hundreds of dollars to the ton.

On account of the poor transportation facilities, provisions are very high, and all over the district men are being laid off until such time as the winter roads are in shape and supplies can be brought in at reasonable prices.

A rich discovery has been made on the property of the Standard Gold Mines Company in the Reserve. The vein is stated to be over twenty feet wide.

What the Government has refused to do, build a spur into Porcupine, will be undertaken by a private company if it can obtain the necessary permission. A number of business men made application a short time ago for permission to form a company and build a private line. The matter is now being taken up with the Government and definite word is expected very shortly.

A very important deal has just been put through whereby Mr. Lorne McGibbon, president of the La Rose, and Mr. Frank Armstrong have acquired the seventeen claims known as the Dobie properties. These were some of the first claims staked in the district, and some good finds are stated to have been made.

Gowganda.—As an evidence of the work being done in the Gowganda and Elk Lake sections it may be stated that altogether forty plants have been installed in those sections. Several of these have been shut down, but there is every possibility of others being installed next winter, and it is likely that some of those not working now will recommence before long. The Hitchcock claims at Elk Lake, which have been incorporated into the Royal Westmount Company, are making a very favourable showing.

The Millerett has shipped another carload of ore, bringing the total shipments since the first of the year to approximately 300 tons.

The deepest mining in the district is on the Reeves Dobie, where high grade ore has been found at a depth of 200 feet. During the coming winter this property will install two Nissen stamps, to reduce some of its low grade ores.

BRITISH COLUMBIA.

The occurrence of ore containing molybdenum at Aspen Grove is reported from Nicola district. The mineral was found there last summer, but not much development work has yet been done on the claim on which it occurs.

Drilling contests are not so frequent at annual celebrations in towns in the mining districts of the province as they were several years ago. At Nelson last month, on Dominion Day, J. Johnson and A. Erickson, of Silverton, Slocan Lake, won the double-drilling contest with a hole drilled in granite 37 3-4 inches in 15 minutes, using 8-lb. hammers and 7-8 inch drills. John Madson and Andrew Selba, of Rossland, were second with a hole 37 1-8 inches deep. A. Erickson won the single drill event with a hole 16 1-2 inches in depth, Frank Johnson, of Salmo, coming second with 14 1-2 inches. Two Rossland boys, Arthur Johnson, aged 13 years, and Fred Chenowith, aged 15 years, gave an exhibition of drilling, making a hole 15 inches deep in granite in eight minutes with 5-lb. hammers and 3-4 inch steel. At Republic, Washington, U.S.A., on July 4, Johnson and Erickson did better than at Nelson three days earlier, for they drilled a hole 39 3-4 inches, as compared with that of 37 1-2 inches drilled by two Republic miners, who won the second prize. The first prize was $200.

Recently a shipment of pig lead from ore smelted at the Consolidated Mining & Smelting Company of Canada's smeltery and refined in its electrolytic refinery at Trail, was made to Kiobe, Japan. This company supplies several lead works in Canada—two in Montreal, Que., and one in Vancouver, B.C.—with lead made from British Columbia ores, for corroding purposes and manufacture into pipe, sheet-lead, shot, etc., and the surplus over the quantity taken by the Canadian market is shipped to the Orient and Australia, chiefly to the former.

East Kootenay.

The Crow's Nest Pass Coal Company is completing, at its Coal Creek colliery, near Fernie, a boarding house for miners, which building, the Fernie "Free Press" states, will probably be one of the best appointed and most comfortable establishments of its kind erected in Canada. The building is three storeys high, a frame superstructure on a stone foundation. It is plastered throughout, steam heated, and lighted by electrity. In it there is accommodation for 50 men, allowing each man a comfortable bedroom, and, as well, there is accommodation for the family in charge.

Operations at the North Star mine, near Kimberley, Fort Steele mining division, yielded a net profit of $11,759.84 for the fiscal year ended May 31, 1910, according to the report of the directors of the North Star Mining Company, lately made public. This report states that "about 3,000 tons of ore was shipped. Mining and exploration work carried on during the first part of the year was encouraging, and an interim report was issued to the shareholders in January, 1910, stating that the work was showing a measure of success, but nothing definite could be announced until further exploration work was done. The work was continued until the beginning of March, and conditions looked encouraging when, unfortunately, Mr. N. McL. Curran, manager at the mine, contracted lead-poisoning and was compelled to resign his position. At the same time scarcity of water and severe snow storms made it impossible to carry on work economically, so it was decided to close the mine temporarily, until weather conditions should improve and the services of a competent man could be obtained." A cash distribution of $26,000, equal to two cents per share, was made to the shareholders on February 1, 1910. The late manager reported that the steam plant and tramway had been kept in running order and buildings in good condition.

Ainsworth Division.

Shipments of ore through Kaslo in June were not large, owing chiefly to a postponement of output of zinc ore from the Lucky Jim mine pending completion of an aerial tramway from the lowest adit down to the Kaslo & Slocan Railway. The Kootenian gives the following as the tonnage figures for the month:—Silver-lead: Rambler-Cariboo, 130 tons; Whitewater, 42 tons; Whitewater Deep, 25 tons; total, 197 tons. Zinc: Lucky Jim, 39 tons ore; Whitewater, 140 tons concentrate; Whitewater Deep, 350 tons concentrate; total, 529 tons. Total of silver-lead and zinc products shipped in June, 726 tons. For six months to June 30, the total output, including both silver-lead and zinc ore and concentrates, was 5,179 tons.

The Kootenay Silver Lead Mines, Limited, has been incorporated with an authorized capital of $2,000,000, half of which is to be treasury stock, to acquire and operate the Highland silver-lead mine and concentrating mill, near the Town of Ainsworth, Kootenay Lake. Up to date there has been about 5,500 feet of development work done on the Highland group. The mine is equipped with an air compressor, machine drills, and all requisite accessories for practical mining and ore production. There is accommodation for about 60 men in the mine buildings. An automatic aerial tramway, rather more than a mile in length, connects the mine and mill. The mill requires eight men to run

it at full capacity of 200 tons of ore per 24 hours, but ordinary tonnage will be about 150 tons daily. Mill machinery is operated by water power. It is claimed that there is in sight sufficient ore to supply the mill for 300 days running three 8-hour shifts. A new adit, starting on the northeast side of the mountain, is being driven; it is in 175 feet and will reach the ore body within 100 feet additional distance. A car load of sorted ore from near the surface of the ore body this adit will cut at depth, returned 72.3 per cent. lead and 25 ounces silver per ton. It is planned to drive another adit from the opposite side of the mountain, after sufficient treasury stock has been sold to provide money for this development, to cut the ore shoots at about 300 feet below the old workings. This work will probably be commenced in August and it will take about five months to drive the 700 feet necessary to reach the ore. A published record of shipments over one period of eleven months shows a tonnage of 2,609 tons with an average of 69.5 per cent. lead and 23.3 ounces silver per ton; gross value, including lead bounty, $111,523.

The West Kootenay Mining Corporation, Limited, lately registered in London, England, intends putting a 10-stamp mill on the Joker group, at the head of the south fork of Kaslo Creek.

Rossland and Trail.

The Rossland "Miner" has announced that it has been decided to close the Le Roi mine. It appears that diamond-drilling and other exploration work has failed to find other large shoots of ore of a grade that can be mined and smelted at a profit. There are still large bodies of ore in the mine, but these are of so low a grade as to make them unprofitable under existing conditions. The managing director, Mr. A. J. McMillan, has gone to England to consult his co-directors as to the future course to the company. Meanwhile work is to be entirely suspended.

The Consolidated Mining & Smelting Company's War Eagle mine, of the Centre Star group, which some time ago was not in nearly so promising a condition, now has ore bodies opened and being mined stated to warrant the claim that it is one of the best gold-copper mines in British Columbia. At no time for years has its condition been more satisfactory, according to the statements of those believed to be well informed, so that the expectation of excellent results seems to be based on good grounds.

At Trail on July 9 a valedictory banquet and presentation were given to Mr. Jules Labarthe, who lately resigned the position of superintendent of the Consolidated Mining & Smelting Company's smelting works and refinery at Trail, to take the management of the Mason Valley Mines Company, Yerington, Lyon County, Nevada, U.S.A. The presentation was in the form of a handsome silver tray, made from silver smelted and refined at Trail. It bore this inscription: "Presented to Mr. and Mrs. Labarthe by the staff of the Trail smelter on the occasion of their departure from Trail, B.C., 1910." In the published report of the proceedings the following eulogy appeared: "Mr. Labarthe has been connected with the big plant at Trail since 1907, and it is largely due to his business acumen and thorough knowledge of the mining and smelting industry in the Kootenay that the plant has reached its present high standard of efficiency, it being one of the largest and best-managed concerns of its kind on the continent."

Similkameen.

The Hedley Gold Mining Company has ordered from the John McDougall Caledonian Iron Works Company, Limited, a 600 horse-power Doble impulse water-wheel, with special needle nozzle and auxiliary relief. This wheel is to be direct-connected to a 350 k.w. generator and is to supply power both for the company's mines and reduction works. The latter consist of the 40-stamp mill built several years ago by the Daly Reduction Company, with cyanide plant, etc. These were acquired last year by the Hedley Mining Company, which has since operated them in conjunction with the Nickel Plate group of mines. The quantity of ore put through the mill last year was about 31,000 tons, from which 16,200 ounces of gold was recovered. This year's tonnage is larger, and the company is paying its stockholders quarterly dividends at the rate of 12 per cent. per annum.

Coast District.

The business office of the Canadian Collieries (Dunsmuir) Limited is to be removed from Victoria to Vancouver. The executive office of the company, which lately acquired the property on Vancouver Island of the Wellington Colliery Company, Limited, will remain in Victoria.

A large occurrence of copper ore in a locality known as Green Lake, situated some 30 miles from the head of Howe Sound, in New Westminster mining division, is being developed. Construction of a railway inland from Howe Sound has been commenced, so that eventually transportation facilities will be available.

The Hidden Creek Copper Company's copper mine at Goose Bay, Observatory Inlet, the latter being an arm of Portland Canal, was recently examined by representatives of the Granby Consolidated Mining, Smelting & Power Company, Limited. There is a very large body of copper ore on the Hidden Creek Company's property, and should the mine not be sold, its present owners plan to erect smelting works near by for the reduction of this ore.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax.—As the result of the disturbance at the Cumberland Coal & Railway Company's colliery at Springhill, the troops have been called for, and several detachments will leave for the scene of the trouble to-day.

For some days past the miners who are on strike have become very restless, and several incipient riots have occurred. The men who are all members of the United Mine Workers of America have been on strike for more than a year, and the management at the mines has been steadily filling their places with men imported from outside points.

From four hundred to five hundred men are working. During the past few weeks the strikers have been ordered to vacate the houses owned by the company, so that they could be occupied by the men at work in the colliery. This was the cause of the recent outbreak. Several hundred of the strikers and their sympathizers have assembled on different occasions and hurled stones through the windows of the houses. The town police and the officers in the employ of the company are unable to control the situation, and the management has asked for the military.

So far no person has received any serious injury, and the damage to the property is not great, but it is claimed that matters are gradually growing worse. On Saturday the representatives of the company made application to Judge Watterson, of New Glasgow, the County Court Judge for the district, for troops, and after the condition of affairs had been placed before him, a requisition for the military was sent to Colonel MacDougall, at Halifax.

The railway authorities at Halifax were communicated with, and arrangements were proceeded with at once for a special train.

QUEBEC.

St. Hyacinthe, July 23.—The news of the blowing in of a gas well of such a flow as to merit the term "gusher" in St. Barnabee County has aroused considerable excitement in the district. The existence of gas or oil has been suspected for many years, the first knowledge that such probably existed dating back for over

seventy years. At that time a farmer, while digging out stumps discovered water bubbling out of the earth and the news became common property in the neighbourhood. Lacking experience and capital, however, the finder allowed the matter to drop.

Some two years ago, Mr. Henri Grenon, hearing reports of the find, visited the Ontario oil fields and there became acquainted with Mr. Lauffer, an expert in oil well operations. Returning to St. Hyacinthe, Mr. Grenon succeeded in forming a small company with Mr. Samuel Girard as president, and Mr. Joseph Langevin secretary. They secured options on seven hundred acres of land and began drilling. Last week Mr. Lauffer, for the first time noticed a distinct odor of gas and immediately made preparations for capping the well when it blew in.

The flow of gas shortly began and is of such a volume as to justify the belief that a valuable gas field lies beneath the company's property. The present pressure at the valve is stated to be steadily in the neighbourhood of 125 pounds, with but very slight fluctuations in the flow. If the flow proves to be permanent there will be enough of the gas from this well to supply the town of St. Hyacinthe with both light and power.

ONTARIO.

Cobalt.—The Dominion Reduction Company has decided to erect a 100-ton custom concentrator on Kerr Lake, to treat the low grade ore from that section of the camp. It is understood that arrangements have been made to erect the plant on the property of the Crown Reserve, and that this company's ore will be the first to be treated. The Cobalt Central mill in that section also treats custom ores, but the location is against its being used to any great extent.

Cobalt.—A thirty-ton car of low-grade ore was despatched from the Little Nipissing, on Peterson Lake, this week, making the seventh shipment since last February. The ore will run in the neighbourhood of 500 to 550 ounces. Besides this car of low-grade, there is a twenty-ton car of high-grade that is being loaded now, and will be shipped this week. The high-grade will probably run over 3,500 ounces, and this is the hand sortings of the winze ore. The management has the work in such shape now that a shipment is expected to be made every month. This will make the eighth car since February, when the mine made its initial appearance on the list of shippers.

Porcupine.—An event in the development of the Porcupine camp occurred recently, when the Timmins mill was started for the first time. This was an initial venture in the history of Porcupine and the whole town awaited the outcome with more than ordinary interest.

The results of the day's operations at the mill were promising.

Considerable satisfaction is expressed at the gratifying outcome of the work on the Timmins properties, and everyone is now convinced that Porcupine, as a gold camp, is here to stay.

It is announced that the Timmins interests have ordered a thirty-stamp mill, and that the same will be installed as soon as it can be got into the mining camp. Such a plant would handle about 200 tons of ore a day, and, with the excellent returns indicated from the day's run, would place the gold field in an enviable position as a large revenue producer.

BRITISH COLUMBIA.

Vancouver, B.C., July 23.—According to Mr. A. D. McRae, vice-president of the Canadian Collieries (Dunsmuir) plans are under way for a rapid development of the coal properties on Vancouver Island.
